MINUTES

A Mr. Mackenzie came to me a day or two
ago. He represented himself as the contractor
who had actually performed the work for the
Union Govt., and asked to be given an oppor-
tunity of tendering for any work that might be
proposed at Kilindini. He said that it was
not necessary for us to send out a committee
to report, as had been done in the past.
But that he could undertake the work himself.
I told him that we had already
decided yes, but said that we would
have to wait to see if the
Union might be approached.

He said that he was going to
write to the Union Govt. and
ask them to give him the contract.
I said that we would be glad to
hear from him if he had any news.

6. Peromyscus stangeri subsp.
♂. Skull only.

Investigation of Flies

in Kenya Colony

Report by Capt. P. S. Kershaw, British
Museum (Natural History) on the
specimens, submitted for identification,
obtained in the collection made in
Kenya by W. N. Vay, Surgeon
for the Chief Medical Officer, Medical
Dept., Nairobi, Kenya Colony.

In East Africa, however, such cases do not appear to give rise to other cases, and while it is always desirable to isolate any possibility of their infecting others, it is certain that it is unlikely that the case which we are considering acquired the disease by inhalation from a previous case. It is also certain that he acquired the disease by being bitten by an infected rat.

The occurrence of Plague, whether septicaemic, pneumonic or bubonic should therefore be taken to indicate that the disease exists among the rats of the neighbourhood. And in practice it is almost always found that it is the rats of the immediate neighbourhood which are affected.

These facts being borne in mind satisfactory measures to prevent the occurrence of further cases can be taken.

These steps are:—

- I. The removal of the infected person to another place and the disinfection of his clothes and blankets in order that those who have to attend to him and to nurse him may run no chance of being bitten by infected fleas.
- II. The removal of any other persons who may be living in the house or hut where the case occurred and, to be on the safe side, the removal of persons from the houses, or huts in the immediate neighbourhood. This is done with the object of removing them from a place where they may be bitten by infected fleas.
- III. The destruction of any rats which may remain alive in the premises on which the case occurred. This is done with the object of preventing the disease being carried to other premises by infected rats wandering in search of food, or through fear, or for some other reason and so infecting the rats of such other premises.
- IV. The destruction of all rats in any neighbouring premises and in fact over as wide an area as possible in order absolutely to prevent any extension of the outbreak.
- V. The destruction of any infected fleas which may be at large on the premises originally infected in order (a) that the re-occupation of these premises by man or person may become infected, (b) in order that on re-occupation or re-infection by rats no rat may become infected.

Suppose that a case of plague occurs in a hut which constitutes part of the labour lines of an estate.

Steps I and II can easily be taken as temporary grass-shelters can at once be erected at some distance.

In East Africa, however, men do not appear to give rise to either bubonic or septicaemic plague, and while it is always desirable to isolate any person who has been infected with any possibility of their infecting others, it is not necessary to do so, because that it is unlikely that the case which we are dealing with has been acquired by disease by inhalation from a previous case, it is almost certain that he acquired the disease by being bitten by an infected rat.

The occurrence of Plague whether septicaemic, bubonic or pneumonic should therefore be taken to indicate that the disease exists among the rats of the neighbourhood. And in practice it is almost always found that it is the rats of the immediate neighbourhood which are affected.

These facts being borne in mind satisfactory measures to prevent the occurrence of further cases can be taken.

These steps are:

I. The removal of the infected person to another place and the disinfection of his clothes and blankets in order that those who have to attend to him and to nurse him may run no chance of being bitten by infected fleas.

II. The removal of any other persons who may be living in the house or hut where the case occurred and to be on the safe side, the removal of persons from the houses, or huts in the immediate neighbourhood. This is done with a view to removing them from a place where they may be bitten by infected fleas.

III. The destruction of any rats which may remain alive in the premises on which the case occurred. This is done with the object of preventing the disease being carried to other premises by infected rats wandering in search of food, or through fear, or for some other reason and so infecting the rats of such other premises.

IV. The destruction of all rats of such neighbouring premises and in fact over as wide an area as possible in order absolutely to prevent any extension of the outbreak.

V. The destruction of any infected fleas which may be of large on the premises originally infected in order that on re-occupation of these premises by man no person may become infected, also in order that on re-occupation or re-infestation by rats no rat may become infected.

Suppose that a case of plague occurs in a hut which constitutes part of the labour lines of an estate.

Steps I and II can easily be taken as temporary grass shelters can at once be erected at some distance.
