# ECONOMICS OF PERI-URBAN ZERO-GRAZING IN UGANDA: THE CASE OF MPIGI DISTRICT

By

## DR. KIREMBE GERALD

## A THESIS SUBMITTED IN PARTIAL FULFILMENT OF THE AWARD OF A DEGREE OF MASTER OF SCIENCE IN VETERINARY EPIDEMIOLOGY AND ECONOMICS,

### **UNIVERSITY OF NAIROBI**

AUGUST 2000

#### DECLARATION:

I, Kirembe Gerald, hereby declare that this thesis is my original work and has not been presented for award of a degree in any other University.

Kunig Signed.

Dr. Kirembe Gerald BVM, Makerere university, Uganda.

#### APPROVALS

This thesis has been submitted for examination with our approval as supervisors: 1. Prof. J. M. Gathuma, B.V.Sc, M.Sc., Ph.D. Signature Date 2/107.78......

2. Prof. J. Opuda-Asibo, BVM, MPH, Ph.D. Signature....t.

Date .... 4/9/1998 ...

# OF PERI-URBAN ZERO-GRAZING IN UGANDA: THE CASE OF MPIGI DISTRICT. DR. KIREMBE GERALD, MVEE.

#### UNIVERSITY OF NAIROBI, 2000.

#### ABSTRACT

This study was conducted using 73 zero-grazing farm units selected randomly in the environs of Kampala City. It aimed at (1) describing the socio-economic characteristics of zero-grazing farmers in the area; (2) identifying their production constraints; (3) estimating variable cost components of zero-grazing and (4) assessing the economic viability of zero-grazing enterprises in semi-urbanised environments. Cross sectional data collected on structured questionnaire was used. Descriptive statistics, analysis of variance (ANOVA), gross margin calculations and Linear regression were utilised to analyze the data. Descriptive statistics provided the mean estimated values of inputs and outputs used by individual study farms. Gross margins gave a measure of the returns to farmers' fixed capital, management and risk. The ANOVA determined whether the established value differences were statistically significant. Linear regression in a causal relationship identified variable farm level factors that explained the significant differences.

Constraints identified by farmers through score board ranking were as follows: Labour requirements (17.0%), Marketing of milk (15.0%), Cost of inputs: Concentrates (12.6%), livestock diseases (12.0%), poor milk yield (11.7%), Periodic fodder shortage (9.0%), Veterinary extension services (9.0%), poor reproductive performance (7.2%), water shortage (2.7%), credit facilities (1.3%), in security of livestock (1.3%), and manure disposal (0.9%). The provision of concentrate feeds at 35.1 percent of the total variable costs was found to be the biggest farm variable cost

component. This was followed by labour at 28.3 percent, forage at 16.8 percent, animal health at 13.4 percent and routine farm services at 6.4 percent.

Dairy enterprise gross margins per year were established to range from Ush -314,214 to Ush 5,600,026, with a mean of Ush. 1,493,259 ( $\pm$ 752,900). Altogether there were fifty-seven farms (80%) with positive gross margins. ANOVA indicated that gross margins significantly differed depending on farmers' access to off-farm sources of income (p=0.005), type of acaricide used on the farm (p=0.009), farmers' education standard (p=0.014), initial source of capital (p=0.028), and distance of the farm from the urban centre (p=0.034). Enterprise gross margins were, however, not significantly different (p>0.05) for sex of the farm owner, breeding method used by the farm, method of manure disposal, land tenure systems, farmers' experience, herd sizes, family size, farm area(s) under forage, total number of milking cows on the farm, farm mean lactation length, labour input in man-hours, and the farm mean daily milk yields.

Modelling revealed that profit (EGM) for a given farm was dependent upon the volume of milk produced per lactating cow per day (p<0.001), milk prices (p<0.001), number of lactating cows on the farm (p=0.001), market channel used to sell off milk (p=0.013), distance of farm from urban centre (p=0.019) and whether farmer used home grown forages or not (p<0.001).

The study concluded that zero-grazing was a profitable farm enterprise (EGM>0) for farmers dwelling in the study area. a possibility of farmers to in crease their profit margins was also established. It is recommended that farmers in peri-urban areas should take up zero-grazing as an alternative source of household income.

#### **BIOGRAPHICAL SKETCH**

The author was born on 28<sup>th</sup> June 1962 in Masaka District Uganda. He attended Rubaga Boys' primary school from 1970 to 1977. He joined Old Kampala Senior Secondary School in 1998 and obtained a Uganda advanced Certificate of Education in 1984. He joined Makerere University in 1985 and graduated with bachelor of Veterinary Medicine in 1989. From, 1992 he joined civil services under the Ministry of agriculture, animal industry and Fisheries. In November 1995 he was registered in the University of Nairobi for a post-graduate degree course in Veterinary Epidemiology and Economics.

#### DEDICATION

vi

This thesis is dedicated to; my parents Mr. and Mrs. Musenze, my wife Annet and our children Julius, Josephine and baby Catherine for the moral support and endless encouragement they gave me throughout the period of this study.

#### ACKNOWLEDGEMENT

I wish to acknowledge all persons in their respective capacities whose support enabled me to complete this study successfully. I sincerely thank and appreciate the useful guidance of my supervisors Professor J. M. Gathuma of the University of Nairobi (UON) and Professor J. Opuda-Asibo of Makerere University Kampala (MUK). I acknowledge all efforts expended on this work by Dr. J. Kilungo (UON), Dr. D. Laker (MUK) and Miss I. Nalukenge (MUK). Special thanks are due to the German Government Exchange Service (DAAD) who offered me a scholarship that enabled me to undertake this study. Here I wish to mention Mrs. onsiski of DAAD office -Nairobi and her colleagues who were my course liaison officers in the DAAD. I am very grateful to Mrs. M. Kabuye and Mr. R. Kintu for the effort they rendered during data collection. I am grateful to the Mpigi farmers for their cooperation and the useful information they provided without which this study would not have been possible. I am immensely grateful to all my lecturers and all the technical staff from the Department of Public Health, Pharmacology and Toxicology, UON, who helped me to do my course work which formed a base for this study. I am also grateful to Mr. Matere for analyzing the data and Mrs. Chenge for helping with thesis typing. Lastly, I acknowledge my course coordinator Dr. M. N. Kyule, my course-mate Dr. a. Odoi, and other fellow Ugandans for their guidance, advice, encouragement and friendship during my stay in Nairobi.

#### **CHAPTER I**

#### **INTRODUCTION**

#### **1.1 Background Information**

Uganda is a small landlocked country on the eastern part of Africa. It has an area of 236,036 Km<sup>2</sup>. One hundred ninety seven thousand Km<sup>2</sup> (>75 %) is dry land area (Ochwo *et al.* 1996). Climatic conditions are mild and over 157,600 Km<sup>2</sup> (>80%) of the dry land area is arable and suitable for farming (World Bank, 1993; Dhalwa, 1995 and MAAIF, 1996). The country has agriculture as its mainstay economically, with over 80 percent of the adult working population engaged in it (Dhalwa, 1995). In the rural setting, agriculture is so important that it employs over 90 percent of the population (MFEP, 1996). Farm units in Uganda, like elsewhere in tropical Africa (Jahnke, 1982), are predominantly of the smallholder mixed type, onto which livestock and crops co-exist (ILRI *et al*, 1996).

Animal management systems in Uganda although vary a lot, similar types of animals are often kept. These include cattle, goats, sheep, pigs, donkeys and poultry. Of all livestock, cattle are the most important in terms of biomass, production and monetary value (MAAIF, 1996). Their population was estimated to be at 5.1 million heads in 1995 (MFEP, 1995). About 3.5 million (>69%) head of cattle in Uganda are located in the southern part of the country, close to or within the Lake Victoria Crescent (LVC) area, south of latitude 1°N. Because of its diffuse dairy activities, this area is normally referred to as the southern milkshed area (SMA) in Uganda (ILRI *et al*, 1996). This area has Mpigi District as its central region. Cattle in Mpigi district, like elsewhere in the SMA are kept for both cultural and socio-economic reasons. They are in most cases integrated with crop farming systems to enable farmers to maintain a certain level of nutrition and

income. Earnings from animals, especially sale of fresh milk, constitute the farmer's main income when crops are out of season. Dairy therefore ensures that farmers get a regular continuous income (MAAIF, 1996). The income from animals, together with other non-crop enterprises, is also known to help salvage families from starvation in case of total crop failure (Jahnke, 1982). Unlike pigs and poultry, cattle consume feeds (fodder) not eaten by man, therefore ensuring that there is no competition for food between man and animals (FAO/ILRI, 1995). Animals also augment crop production in crop-livestock mixed smallholder systems by providing manure and draught power (Jahnke, 1982).

Milk in Uganda is the most important source of animal protein for low income earners (MAAIF, 1996). This is particularly in urban areas where beef is expensive and is generally not affordable (Sabiti, 1994). Livestock enterprises in general also give increased economic stability to households as they act as a cash buffer and hedge against hard cash devaluation (FAO/ILRI, 1995). These advantages vis a vis benefits associated with livestock farming, together with the fact that prices of milk in Uganda have been rising, have given farmers confidence to continue investing in dairy enterprises in the form of zero grazing. However, the low financial returns per livestock unit hardly meet the capital invested (MAAIF, 1996). The economic viability of the dairy enterprise in the form of zero-grazing in Uganda are thus doubtful. The need therefore arises to carry out constant periodic reviews on the industry's performance in order to ensure that it thrives economically, and remains sustainable, particularly so in urban environs where traditional farming methods are rapidly disappearing due to urbanization.

#### **1.2 Problem Statement**

Milk production in Uganda is still comparatively low, and ranges from 6-15/ per cow per day compared to over 20/ which is the mean genetic potential of the exotic dairy animals (Sabiti, 1994). The constraints to increased milk production in Uganda have been found to include: shortage of farm inputs such as forage, water, pasture seeds, lack of capital and market opportunities, and the presence of livestock diseases (MAAIF, 1993 and Suzuki, 1994). In addition, the dairy industry in Uganda suffers from information gaps, with no comprehensive data available (MAIF, 1988, MAAIF, 1993 and Nalule, 1996), and even the little information that is available is known to be sparse and highly unreliable (MAAIF, 1996). Dairy animals are also generally poorly managed in Uganda as a result ignorance on the use of locally available dairy resource inputs (Sabiti, 1994). Despite the recognition of these problems, very little dairy related production research has been carried out to seek solutions to the problems (MAAIF, 1993). Moreover, the majority of farmers in Uganda have limited resources to undertake formal research on their own. These factors have led to a situation where farmers adopt new technologies due to group influence without considering consequences. Zero-grazing, as a new technology, has fallen prey to this anomaly. Promotion of this industry has been further disadvantaged by the fact that traditionally, farmers have not practiced zero-grazing (Kalule-Sewali, 1994). The Ugandan farmer therefore lacks knowledge on zero-grazing practices, particularly so on implementation, its effects on the environment, resource requirements and how the available resources can be optimally utilized. Interest also exists for knowing how zero grazing can be integrated with other pre-existing dairy production systems. It is also still doubtful whether this new technology can survive as an independent economic enterprise (MAAIF, 1996). Farmers that invested in it also desire to know

whether it really pays economically. This is especially so in the peri- and intra-urban environs of LVC where most zero grazed animals are concentrated, and yet essential dairy inputs such as feeds and labour are costly due to existence of other alternative uses. This study was undertaken to seek solutions from the farmers' economic point of view. The peri-urban areas of Kampala City (located in Mpigi District) were used as study areas for zero-grazing in peri- and intra-urban environs in central Uganda with special reference to the LVC area.

#### 1.3 Research Objectives

#### 1.3.1 Broad Objective

To assess the economic viability of zero-grazing dairy enterprise in the peri-urban farming systems in central Uganda.

#### 1.3.2 Specific Objectives:

(1) To describe socio-demographic characteristics of farmers engaged in zero-grazing and type of livestock management practiced.

(2) To identify production constraints farmers engaged in zero grazing face.

(3) To identify inputs used by zero grazers in semi urban environs and establish their relative contributions towards total enterprise variable costs.

(4) To carry out a financial analysis to establish whether zero-grazing is a profitable enterprise in semi-urbanized parts of Mpigi district.

#### 1.4 Hypothesis

The following hypothesis was tested in this study: that zero-grazing is a profitable enterprise in semi-urbanized areas of the southern milkshed region of the lake Victoria Crescent i.e. enterprise gross margins are positive.

#### 1.5 Organization of the Thesis

This Thesis is divided into six chapters. Chapter I gives the introduction of the study, problem statement, objectives and hypothesis tested. It describes also why the study was considered important to farmers, researchers and policy makers. Chapter II covers a review of literature relevant to this study. In Chapter II, a description of the procedures that were used to accomplish the set objectives is given. An explanation of data needs, and collection and analysis is given, too. Chapter IV presents the results of the descriptive statistics while Chapter V presents results from financial analysis and linear regression. Chapter VI contains conclusions and recommendations drawn from the study.

#### 1.6 Significance of the study

This study contributes information on commercial livestock production in the milkshed of central Uganda with special reference to farmers practicing zero-grazing in urban environs. The study highlights the constraints of zero-grazing as a sub-method of dairy production system. It seeks solution and suggests practical recommendations to farmers to help resolve identified problems. New knowledge concerning implementation of zero-grazing, its resource allocation and use are provided to farmers. Some existing information gaps on dairy, and zero-grazing in

particular, within the studied area are bridged. The study also provides a resource of demographic and socio-economic parameters pertaining to farmers who practice zero-grazing in the study area for agricultural extension staff and researchers. This study contrasts with all previous study approaches on zero-grazing in the study environs, since:

(1) the systems of interest are purely livestock orientated with animals intensively managed

(2) the study area is peri-urban with a high human population pressure on land.

(3) the study concentrates on very small holders with a maximum of four lactating cows.

(4) economic assessment is based purely from the farmers' economic perspective.

#### **CHAPTER II**

#### LITERATURE REVIEW

This chapter gives a review of available literature considered relevant to this study. First, a theoretical background on the concept of resource use in agricultural production is given. Next, it cites a number of studies, which have attempted to shows that introducing better farming methods as a new technology can improve human welfare in developing countries.

#### 2.1 The Concept of Profitability

Production was defined by Rhodes *et al.* (1968) as a process whereby certain goods and/or services are turned into different forms. The goods and/or services used are called resources or inputs whereas the goods and/or services created are called goods, outputs or products. The purpose of changing goods and/or services into different forms centres on the fact that goods/or services can have their valves enhanced by increasing their utility in a society. The rationale is therefore to use goods/services which have low utility to produce others that are of high utility for consumers. The difference in value between the input and created goods and/or services serve as an incentive for the producer. This is loosely refereed to as profit in production. So universally before producers attempt to produce any product they consider the cost of resources at their disposal and the likely valve of the goods and/or services they are poised to producer. In agricultural the farmers often produce what is most convenient depending on local resource endowment, principal of comparative advantage. Resources, which are readily available, free or of low value are abundantly exploited while scarce, expensive or limited resources are sparsely, used (Ackello-Ogutu and

2.0

Wachi, 1990). Under farming conditions, the producer through guessing, observation, uncontrolled farm trials and informal experiments learn and establish what are the right relative amounts of inputs and out that achieve desirable results. In the long run producers in the same area using similar outputs and producing similar outputs therefore establish a plane of production onto which they oscillate (Price, 1991). Moving out require additional use of inputs or an increase in the efficiency of current resource use. This can be in a form of new technology.

#### 2.2 Relevance of Economic Principles to Farmers

According to Makeham and Malcolm (1986), the starting point in understanding why economics is of real life relevance to farmers is that there is not much sense in doing something if the end result is that one ends up being in similar or worse situation than the initial stage. This implies that farmers consciously engage in farming activities, which have social and/or economic benefits. The inference here is that rationality and opportunity benefit maximization forms the key principles in all economic endeavours. These principles are applicable to all people, regardless of where and how they live, for both developed and under developed countries (Barnard and Nix, 1979; Ackello-Ogutu and Wachi, 1990 and Panin, 1993). Decisions made by farmers are based on these principles depending on farmers' objectives and goals.

#### 2.3 Farm Goals

Households constitute the key decision making units in rural settings where subsistence and/or semi-subsistence is the main form of agriculture (Ahmed and Rahman, 1992). Household objectives were identified by Belete *et al.* (1993) as primarily to secure subsistence survival, and at

the same time to maximise profit from the sale of the household surplus produce. However, it should also be noted that as one moves away from subsistence through semi-subsistence into commercial farming, profit maximization gains at the expense of pure subsistence survival (Ackello-Ogutu and Wachi, 1990). Farming families therefore have clear objectives in deciding whether, what, how and how much to produce (Reynold, 1996). The farm objective is not simply increased marginal profit.

#### 2.4 Contributions of Economics Towards Livestock Production

According to ILCA (1989), economics contributes to the improvement of policy formulation and decision making for animal health projects and programmes, by explaining factors which influence livestock producers, how they decide what and how much to produce, what prices are acceptable to them, why production is expanded or contracted, and how much they should invest. It is also used to analyze how producers of livestock interact with consumers of livestock products. It can also be used to predict the likely consequences of changes in the livestock sector, hence impacts of changes can be assessed before specific policies are implemented. Economic analysis is also used in livestock project priority ranking. Project prioritization is essential in developing countries where resources are limited, and there is a need to ensure that only those projects that are economically viable are implemented (ILCA, 1989 and Oakley, 1997).

#### 2.5 Factors Affecting Animal Production

There are many factors, which influence animal production. In dairy animals, however

these factors are all subject to the interaction of: (1) the animal's genome (thus at the farm level one has got to consider the animal's breed and type) and (2) the environment; this encompasses two broad aspects\_the climate and management (Radostits *et al.*, 1994).

Management factors are most important for individual farmers because they can be easily manipulated at the farm level to achieve desired outcomes. Factors, which determine outcomes, are known as variables, and their cost values are known as variable costs. Farmers as decision makers striving to operate efficiently, must identify farm variable costs that are most relevant in determining the levels of production in their enterprise in order to achieve set farming goals (Oakley, 1997). In livestock enterprises the variables which are important in explaining production are: concentrate feeding; pasture acreage and type of fodder, use of farm by-products and farm operating capital (Murithi, 1990; Sharma and Singh, 1993; WIIAD, 1994 and Oakley 1997,). Operating capital for dairy enterprises includes the monetary value for mainly replenishable farm inputs such as chemicals, mineral licks, drugs, vaccines, acaracides, and routine farm services (Radostits *et al.*, 1994). The latter are largely in the form of treatments and inseminations. The relationship between inputs and milk production in dairy systems is often examined by researchers by identifying factors that affect production critically, functional relationship analysis.

Murithi (1990) using this approach identified inputs on dairy farms that influence milk production to be:

(X<sub>1</sub>) Concentrate (kg) fed per animal per year.

(X<sub>2</sub>) Labour (man-hours) per animal per year.

(X<sub>3</sub>) Area (ha.) under forage per animal per year.

(X<sub>4</sub>) Farm by-products (kg) fed per animal per year.

(X3) Operating capital (kshs.) used per animal per year.

The model obtained took the following form:

$$y = A. X_1 B' X^{B} 2 X_3 3. X^{B} 4 S^{B} 5 E$$

Where  $B_i$  is the specific input regression coefficient and E is an statistical error term. Of all the inputs (X<sub>i</sub>), concentrates i.e (X<sub>i</sub>) had the highest  $B_i$  values indicating that change in the levels concentrate feeding would effect milk yield most.

Kilungo (1998) in a study in Kiambu district of Kenya also used the production function approach to identify factors that influence milk production. The results showed that at 90% confidence level that factors include concentrates, hired labour, forage, and farm operational capital. It was also interestingly revealed that concentrate and forage consistently had coefficients of positive quantitative signs, implying that forage could be substituted with concentrates or vice verse to a certain extent in diets of lactating dairy cows. These findings are in parallel to those of Nalule (1994) who reported dairy cows with satisfactory milks yields on a diet devoid of concentrate. In central Uganda, of which this current study is part, household refuse, particularly banana peels are exploited by farmers as forage for animals.

#### 2.6 Tools for Analyzing Farm Profitability

Many analytical tools have been developed over time for use in economic studies. These include: gross margin analysis, partial budget analysis, cost-benefit analysis, decision tree analysis, functional analysis, linear programming, dynamic programming, the Markov chain and complex composite analysis tools like system simulations models. For examining agricultural farm enterprises the analytical tools which are of value and significance according to Makeham and Malcolm (1986) are gross margin analysis, partial budget analysis, costs-benefit analysis, decision tree analysis, and function analysis. The selection of one tool and not the other(s) or combination of two or more is subject to the scope and duration of the study, whether it be farm level or national analysis, farming systems analysis or the study of specific enterprise or programmes and/or the study is over one year or a number of years (Oakley, 1997). The selection of one tool and not the other(s) or combination of two or more is subject to the scope and duration of the scope and duration of the study, whether it be farm level or national analysis, farming systems analysis, farming systems analysis or the study of specific enterprise or programmes and/or the other(s) or combination of two or more is subject to the scope and duration of the study, whether it be farm level or national analysis, farming systems analysis or the study of specific enterprise or programmes and the study is over one year or a number of years (Oakley, 1997).

#### 2.6.1 Cost Benefit

This is a procedure of determining the profitability of programmes over a period of time. Future costs and benefits are "discounted" to make amounts occurring at different points in time completely comparable. The results are expressed either as a differences of sums (net values) or as a ratio (benefits:costs ratio). The relationship between costs and benefits can also be expressed as cost-effectiveness when benefits are extremely difficult to quantify as in social programmes. Both cost-benefit and cost-effectiveness have been used a lot in developing countries during the process of project prioritisation (ILCA, 1989). Cost benefit analysis, according to Oakley (1997), is suitable for periods of time between five and ten years.

#### 2.6.1 Partial Budgeting

This is quantification of the economic consequences of a specific change in farm procedures. It involves examining the following four: (1) Additional revenue realised form the

change; (2) Reduced costs as a result of the change; (3) Revenue foregone as a consequence of the change and (4) Extra costs incurred due to the implementation of change. Decision is made to adopt the change if the sum of (1) and (2) is greater than the sum of (3) and (4). Partial budgeting on the farm is, as rule, considered if changes are minor. For example when a farmer is culling an animal with an fertility problem (Martin *et al.*, 1987).

#### 2.4.3 Decision Tree

This is defined as any framework used as a strategy for handling complex decisions so that they can be reviewed for being readily evaluated by the human mind (Rhodes *et al*, 1968). Choice such as whether to intervene or not are presented visually. Probability concepts are then used between contrasting options. Eventually a tree form is formed which diagrammatically represents the problem solution and possible limitation. This helps the mind to explore all consequences of possible decisions. The final decision is then taken on the criteria of monetary valve and expected utility of the outputs. In livestock the decision trees have been used in the poultry industry to evaluate the economies of poultry disease control programmes, Carpenter (1980), quoted by Martin *et al.*, 1987.

#### 2.4.4 Gross Margin Analysis

Gross Margin Analysis (GMA) is the most practical method for assessing enterprise profitability, and determining the importance of an enterprise in a mixed crop/livestock production system (Martin *et al.*, 1987). It is most frequently used for livestock enterprises (Makeham and Malcolm, 1986). It is particularly recommended for examining farm performance especially if

profitability of enterprise(s) is the point of interest (Dedertin (1986) as quoted by Omore (1996). Gross margin is defined as the value of enterprise output less the variable costs attributed to it (Oakley (1997). It is symbolically presented as shown by the formula below:

$$GM = (\sum_{i=1}^{n} Y_i * P_{y1}) - \sum_{i=1}^{n} (Xi * P_n)$$

Where:  $\Sigma(y_i^* p_{y_i})$  is the gross income of the enterprise obtained as a sum of the quantities of products produced (y<sub>i</sub>) multiplied by their prices (p<sub>yi</sub>).

The  $\sum(x_i * p_{xi})$  are the total variable costs obtained by taking quantities (x<sub>i</sub>), monetizable farm inputs which are directly related (varies) to the farm outputs and multiplying them by their respective prices (p<sub>xi</sub>).

#### **Gross Incomes**

In livestock enterprises gross incomes, according to Barnard and Nix (1979), are made up of two main farm events. The first involve changes in the farm livestock inventory. This shows how much stock (monetised animal value) the farm has at the end (at hand) less what it had at the start of a specified time period. A one year period is recommended for stall-fed farm animals. The value of animals and animal products consumed by the household without selling for cash are also considered. The second event includes cash sales of farm animals or/ and outputs. This constitutes all monetizable outputs from the farm such as sales of animals, animal products, animal draught power, and animal by-products.

#### Variable Costs

Makeham and Malcolm (1986) stated that consideration of the variable costs of any livestock farm activities must reflect on the following: (1) Feeds\_ these include costs of forage crops, silage, purchased feed, home-grown grains, maintaining improved pastures, payments for grazing, and direct labour costs involved in watering and feeding the animals; (2) Husbandry i.e medicines, cleansing materials for milking sheds and utensils, and veterinary services; (3) Breeding services and costs of replacement stock where they (animals) are not reared on the farm and (4) Marketing (i.e. transport, processing and selling the produce).

#### 2.4-4.1 Advantages of Gross Margin Over Other Tools

Gross margin is a user-friendly economic analytical technique. This is so because it offers simple straightforward results. According to Price (1991) results expressed in complicated scientific terms carry little meaning, if any, for lay farmers. Thus, frequently such results are not understood and end up having no impact on targeted farmers. Ellis and James (1979) and ILCA (1989), working with gross margin observed a number of advantages too. First, gross margin is the most practical and simple method for assessing enterprise profitability, and offers a good comparison of different enterprises. Second, it is also widely used in farm management studies and therefore readily understandable by most people. Martin *et al.* (1987) also emphasizes this advantage of Enterprise gross margin. Third, the method can also be used to estimate the effects of change (sensitivity analysis) within the limits of fixed assets and resources available to the farmer. Fourth, gross margin can also be used to test technologies before scarce resources are committed to production (ILCA, 1989). According to Martin *et al.* (1987), identifying and categorizing costs at farm level for obtaining gross income and variable cost components is considered to be advantageous for the farmer, as it is known to give the farmer an idea of the size of the change in costs that would occur if one or more activities on his/her farm were to contract or expand. Because of its many advantages gross margin analysis was also adapted in this study too.

#### 2.4.4.2 Computation of Gross Margin

Gross income minus variable costs is a straightforward calculation. It simply requires the listing of all the various components of the farm's gross income (output) and variable costs the farm incurs. The problem with this approach however is that it involves the identification of the components on an individual basis (Makeham and Malcolm, 1986), and one is compelled to decide on what type of price to use in computing the results. For the purpose of this study the milk producer farm gate and animal sale prices were used to compute enterprise gross income. Similarly, farm variable costs were established by using the prices of individual items purchased and used by the farm.

#### 2.5 Economic Assessment of Smallholder Farming Systems

A number of research studies have been carried out in developing countries to ascertain whether small-scale farmers benefit economically by taking on new technology. The designs and economic tools used in these studies varied depending on the local conditions where the study was conducted, the economic theory behind the assessment and research hypothesis tested. Findings from some of these studies are reviewed here. Attention is given to those carried in East Africa, where this study took place. Kalule-Sewali (1994), evaluated the performance of a zero-grazing project in central Uganda. Her objective was to establish whether aid extended to women in kind (in-calf heifers) would improve women livelihoods. Data was collected from 40 purposively selected households with zero-grazed animals and summary statistics worked out.

The result showed that the women managed to raise their household incomes through the sell of milk. They also improved on the welfare of their families by being able to meet sundry expenses in the home. The nutritional status of the families with lactating animals was also found to be superior. Milk intake was over 96 litres per household member per year of the cow owner family as opposed to 22.41 the per capita intake of milk in Uganda. The study also established that zero grazing enable farmers to integrate animals and crop as manure could easily be harvested.

The researcher, basing on these results, concluded that zero-grazing as a new dairy system could assert a positive economic impact on smallholder farming, stabilize household income(s) by providing a daily income in form of milk sales, improve food security through increase food production, and control malnutrition.

The sample of farmers used in this study was however gender biased, as all the study farms were owned by women. Farmers also got initial cows free of charge from the project and all the animals were of high milk production potentials (pure exotic animals). For many farmers in Uganda these conditions are a rarity. The study nevertheless showed that zero-grazing was a potentially viable enterprise in Uganda.

In southern Uganda, a study similar to that of Kalule-Sewali (1994) was carried out by Nalule (1996). The objective was to assess whether zero-grazing was profitable where milk prices

are comparative low. The researcher during a cross sectional study examined the relationship between inputs and outputs to measure economic performance of households. Results were presented in form of ratios (Benefit/cost) or/and as summed up differences (gross margins). Gross margin was established to be ranging from -712,000 to 5,230,000 /=. The differences in values were established to depend on the levels of milk production, sex of the calf sired and on whether farmer managed to sell off the calf born within the year. A sharp difference in benefit/cost ratio was observed between the farmers that had started with donated cows (B/C = 1.98) and those that had purchased their own animals (B/C = 1.32). This difference in B/C registered was shown by the researcher to be due to differences in milk production between the cows that were donated and those purchased by farmers. The donated animals were largely pure exotic as opposed to the purchased ones, which were cross-breeds. The researcher, basing on B/C ratio obtained and gross margin values concluded that zero-grazing was a profitable venture, even when milk prices were quite low (250/- per litre), and recommended zero grazing as a new practical technology to improving dairy farming in Uganda.

One unique feature of this study was that feeding of concentrate was very limited (5%). Instead of concentrate, farmers relied heavily on cheap readily available farm bi-products. In respect to the current study area, milk prices are high because of demand by the elite population in nearby urban centres. The provision of concentrates is also high due to land resource shortages. Farmers in the study area also had an opportunity to use an intensive extension service system, which is non-existent in the present study area.

In a study to determine the profitability of different farm enterprises, Laker (1999) assessed the economical justification for routine treatment of dairy animals against trypanosomiasis. Fifty farms randomly selected from a sampling frame of 187 dairy farms and stratified by herd size were used. The assessment involved estimation of total cost of disease as a component of farm variable costs. The researcher, using simple herds spreadsheet models, estimated the economic cost on farms due to trypanosomiasis to be negligible. Only Ush. 1,900, 1,300 and 700 annually for small, medium and large herds respectively. Basing on this finding the researcher concluded that trypanosomiasis comparatively was not as major a constraint in the study farms as originally thought. He therefore recommended that the government policy of carrying out routine chemoprophylaxis at specific interval irrespective of the  $\leq$ - fly challenge, and disease risk in different production system as a new technical measure needed re-evaluation.

This study revealed that some farmers might actually maintain or take on new technological innovations, which are not economically justifiable. It highlights the need to periodically conduct research and up date information on farming systems. In respect to the present study zero grazing is a newly introduced technology and operated on recommendations drawn from different geographical areas. It is therefore worth while to examine production systems in new areas to diagnose problems which are peculiar in location. A system of production is best examined using the " systems approach" whereby all the production components and their inter-linkages are considered in totally. Practically this is limited by the scarcity of resources and time available for research (Martin *et al*, 1987). So in most cases researcher examine only one or a few components of a given production system and draw conclusion whether to recommend or not.

Wange (1998) in a study "studies on primary tillage implements and systems used for draught animal cultivation featuring Uganda situation" examined ways for improving farm profitability through new technology and changes in animal management systems. The study was in form of a basic analytical review of literature on the performance of animal drawn implements. An old type of plough drawn by one ox was compared with a broad plough drawable by a team of two oxen, which could be introduced to farmers. Operational costs were estimated and income realizable projected for the two systems. The results showed that farm total revenue could increase by introducing the new plough by 29.7% due to improvement in crop yield. Basing on this the use of a bigger plough drawn by several animals was found to be both technically and economically feasible. The researcher therefore concluded that it was potentially worthwhile to farmers to invest in the new plough. For the future the researcher predicted that changes in animal use would will directly lead to increase in standard of living of the farmers and income in the area.

Curry *et al.*, (1996) conducted a study on dairy in relation to human welfare in Kwale and Kilifi District, Kenya using data from 779 households. The objective was to assess whether human nutritional status and health had improved as a result of new technology in form of dairy intensification. A longitudinal survey was conducted to monitor status of the community at different points between July 1985 and 1987 using anthropometric parameters. Points of articulation between livestock and nutritional systems in households included income, resource allocation, food consumption and human disease risk. The main finding was that the potential nutritional impact of increased livestock production depends on the direct consuming of milk by families with cows. It was also established that milk is nutritionally important for dairying households, as it provides essential amino acids, fat, vitamin A and calcium, which are always deficient in most African diets. An intensive dairy production system was also observed to create employment opportunities, and result in the reduction of the consumer price of milk too. This study clearly reveals that intensification of dairy production can exact impact on people facing land

constraints, and that the system has many advantages and benefits which are not easily quantifiable into monetary values. In the present study area, unlike in Kilifi, the population is urbanite. Milk is produced for both income and feeding the families member. A female family member often provides most of labour (MAAIF, 1996).

Mullins *et al.*, (1996) examined the intensification of dairy in coastal Kenya from a gender point of view. Cohorts of 16 female and male farmers were formed and socio-economic and production characteristics data collected. The data when analyzed showed that 48% of work in the dairy unit is done by women, while the labour contribution of men in both cohorts was relatively small. It was also shown that dairy intensification had positively increased both women's personal income and household income. There was also consensus that human welfare had generally improved at household level as a result of the intensifying dairy enterprises in the area. Positive changes in social well being associated with changing animal management systems have also been reported Omore *et al.*, (1997).

## **CHAPTER III**

#### .0

## MATERIALS AND METHODS

This chapter describes the general area where data for this research was collected and a escription of the procedures used to analysis it

## 5.1 Study Area3.1 Study Area

## .1.1 Geographical Location

Uganda is administratively divided into 45 units called districts. Mpigi, where this study was arried out, is one of them. The district is located on the northern shores of Lake Victoria sharing orders with four other districts. Luwero in the north, Mukono in the east, Masaka in the west, and 4ubende in the north west. On the eastern part, Mpigi district also surrounds Kampala, the largest and nost densely populated (1.5 Million) city in Uganda. Mpigi District as a catchment area of the city is lso densely populated (MFEP, 1992; Sabiti, 1994). The geographical location of Mpigi District is hown in figure 3-1.

**MAP OF UGANDA** 

23

## 3.1.2 Administration

Politically, Mpigi District is divided into several sub-administrative units: 5 counties and one municipality, 35-sub-counties, 256 parishes and an unspecified number of villages. The sub-county forms the key political administrative unit in the district, and it is headed by a sub-county Local Council Chairman (LCC). All local public servants serving within the sub-county, including agricultural extensionists, are answerable to the LCC.

## 3.1.3 Zero-grazing Enterprises

In Mpigi District, like in all other parts of Uganda, people are engaged in agriculture, which is a mixture of crops and livestock. Animals are therefore found everywhere and smallholder livestock management systems are a key feature. However, as a rule, intensive systems of livestock production are associated with urban environs. Zero-grazing activities in Mpigi District are therefore concentrated mainly in peri-urban parts of the district (areas adjacent to Kampala City), and within or around towns inside the district (DVSAI, 1996). This study purposively focused on these areas (Figure 3-2).

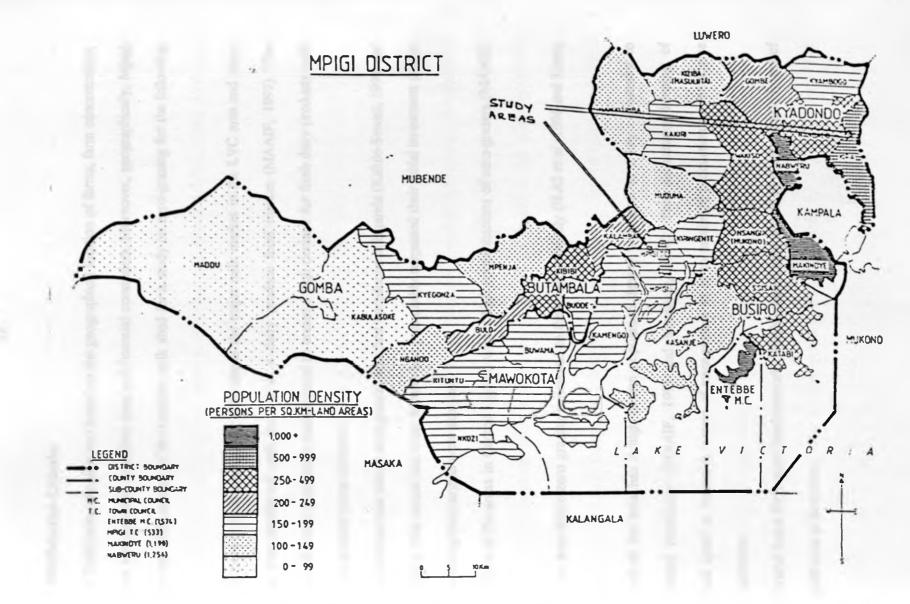

Figure 3-2: Map of Mpigi Showing the Study Areas

3

#### 3.1.4 Site Selection Criteria.

Study area selection was based on the geographical location of farms, farm concentration, time that was available to collect data and financial constraints. Moreover, geographically, Mpigi District was ideal as part of the southern milk shed for a study on zero-grazing for the following reasons:

1. Its proximity to Kampala City. The city is the major milk market in the LVC area and zerograzing was established with the city as a dairy produce focal market (MAAIF, 1993). The presence of a vast population was assumed to create a high demand for fresh dairy products with fairly high market prices for them.

2. It is a pioneer area where zero-grazing was first introduced in Uganda (Kalule-Sewali, 1994 and HPI, 1992). This meant that most farmers had presumably surpassed their initial investment phase, and positive gross margins were expected.

3. It is one of the areas in Central Uganda with a high concentrations of zero-grazers (MAAIF, 1996).

4. It is an area where zero grazing is believed to thrive economically (ILRI et al, 1996 and Kinte, 1997).

5. Much of the area has a high human population density with land as a key constraint to agricultural production (MAAIF, 1993 and Mwebaze, 1994). This necessitates keeping of livestock under an intensive system of management so as to maximize production on the scarce land resources.

6. The area has a fairly good road network, which enabled easy access to it with simple forms of transport such as bi-cycles.

#### 3.2 Sampling

# 3.2.1 Selection of Study Sites and Subjects

Selection of the study areas (sub-counties) was guided by an inventory of commercial livestock farming activities in Mpigi District kept at the Veterinary District Headquarters, which showed that the area has a high concentration of zero-grazed animals (DVSAI, 1996). All the sub-counties located within the 5-20 km radius outside Kampala City, Entebbe municipality and Mpigi town, the key urban centres in the study area were considered and designated as peri-urban for the study. Nine sub-counties, Nangabo, Nabweru, Nsangi, Sissa, Makindye, Kira, Katabi, Entebbe and Mutuba 1 Mpigi comprised of the area.

Using a simple random sampling technique, Mutuba 1 Mpigi and Kira sub-counties were selected to constitute the study sites. Geographical location of farms and the socio-demographic characteristics of the study farmers in the two sub-counties were then used to group the study sites into the two zones, zone one (zone I) and zone two (zone II). Farms in zone I were located in parts of Kira sub-county closest to Kampala City (<5 km), in areas with a high human population pressure on land of over 500 persons per km<sup>2</sup>. Farms in zone II were located further away from Kampala City (>5km) in either Kira or Mutuba 1 Mpigi sub-counties in areas which had relatively low human population densities of less than 500 persons per km<sup>2</sup>. Boundaries of the created zones corresponded with political, administrative boundaries at parish levels.

#### 2.2.2 Sample Size Determination

In research work the sample size (n) required for estimating the means of livestock dependant quantitative variables is given by the following formulae:  $n = Z^{2*}S^2/L^2$  (Martin *et al.*,

27

(1987).

Where:

n is the appropriately desired sample size.

 $Z^2$  is the square of the reliability coefficient for a fixed level of statistical confidence. This is normally put at 95 percentage (Z = 1.96) in most biometric studies (Lachin, 1981).

S<sup>2</sup> is the variance of variable(s) under estimate.

 $L^2$  is the square of the allowable error.

In the dairy enterprise, milk is the most important component of farm produce contributing towards sales, hence income. This is supported by findings by Murithi (1990), MAAIF (1993), Kalule-Sewali (1994), Ntegua (1994), ILRI *et al* (1996) and MAAIF (1996). Since farm incomes are directly proportionate to enterprise gross margin, which is also dependant on milk produced by farm, milk production levels on farms could give a better alternative for sample size determination instead of enterprise gross margin which is known to be very variable especially on small holder dairy farms in Uganda (MAAIF, 1996). Lachin (1981) recommended that it is necessary for researchers to adjust the sample sizes (n) obtained by statistical consideration upward to a factor (N<sub>d</sub>) to cater for subjects that drop out of the study as researchers collect data in the field (Lachin, 1981). N<sub>d</sub> is given by the formula: N<sub>d</sub>=n/(1-R)2. Where N<sub>d</sub> equals the sample size after adjusting for losses of an estimated (R) proportion of study subjects. A value of 15% (R=0.15) is normally used.

The sample size (n) required for the study was calculated:

With Z<sup>2</sup>=1.96, S<sup>2</sup>=7.67, L<sup>2</sup>=0.75.  $n = (1.96)^2 * 7.67/(0.75)^2 = 52.4$  These results showed that a minimum of 53 farms were required to carrying out this study. Using Lachin's (1981) approach, the required field sample size (N<sub>d</sub>) needed to give a minimum sample of study 53 units was computed by assuming an expected dropout of 15% farms (R=0.15). Substituting in the formulae:  $N_d=N/(1-R)^2$ .

$$=> N_d = 53/(1-0.15)^2 = 73$$

A total of 73 farms were thus selected randomly for data collection."

#### 3.2.3 Reference Population

These are small holder dairy farms in the southern milk-shed areas of the Lake Victoria Crescent (LVC) of central Uganda undertaking zero-grazing practices in urban environs. Small holders dairy farms for zero-grazing were defined as farm units with a total of five or less lactating cows per year, with animals (cattle) kept and fed permanently in stalls. Only animals that were registered by the resident local veterinary sub-county in-charge(s) were considered. In all, a total of 318 farm units were identified to satisfy the study description of zero-grazing in the two sub-counties selected to constitute the study area. These served as the study reference population.

#### 3.2.4 Study Sample Population

The study sample population consisted of 73 farms obtained by simple random sampling from 318 zero-grazing holdings in the reference population. The number of animals, geographical proximity and human population density in a parish area were used as a mean of stratification to

The variance (S2 = 7.67) and allowable error (L2 = 0.75) equated above were derived from figures of milk production which were obtained in a survey by MAI&F In the study area in 1988 (Uganda MAI&F, 1988).

divide the study area into two (02) zones. For each parish, a proportionate number of animals were included in the sample frame. Individual farms were identified using records kept by resident agricultural/veterinary officials. The physical locations of the farms were then established through the assistance of sub-county local civic leader(s). Table 3-1 shows the distribution of sampled farms. Farms in zone I are indicated by "\*" sign.

Table 3-1: Location	of Study	Farms	by Zone
---------------------	----------	-------	---------

#### 3.3 Field Work

#### 3.4 3.3.1 Research Tools.

Tools used in this study included land area measuring equipments: pocket compasses, measuring tapes, nylon cords and poles. Buckets, measuring cylinders and plastic cups were utilised for capacity measuring (volumes). Pocket calculators, paper and pen were used in working out simple sums. Computer software packages: SAS, Dbase and Word Perfect were used for data analysis, writings and printing reports.

## 3.3.2 Surveys

Initial reconnaissance surveys were undertaken by the investigator between December, 1996 and March 1997 to establish cordial relationships with the local participants. These included farmers, government administrators, civic leaders, agricultural extension officials both government and private, and animal interest groups such as livestock donor agencies. Informal introductory interviews were held with each of the above groups to get an over-view of the farming situation in the study area. Special interest was given to zero-grazing activities especially in peri- and intraurban environs. Local inputs such as an interpreter, enumerators and foreknowledge on the use of public facilities were sought at this level. Further subsequent visits were paid to these local agents, whenever it was deemed necessary.

## 3.3.3 Data Collection

Data was collected between June 1997 and 30th October 1997 by two trained enumerators

31

who were supervised by the investigator. Both primary and secondary data were collected. Primary data was collected on pre-tested structured questionnaire (Appendix 1), supplemented by secondary data from the farmers' record books. The data collected was broadly of two categories: socio-demographic data of the farmers and farm production data. Socio-demographic data of the farmers provided explanatory variables while farm production data was concerned with expenditure and income for the farmer relating to zero-grazing activities.

## 3.3.4 Information Generated

Information generated on farm owner was on sex, marital status, experience, access to offfarm jobs and educational level; while information on the farm was on location of the farm, source of initial capital, source of forage, type of acaricide used, breeds of lactating animals kept, market outlets for selling farm produce (milk), breeding methods used, prices of produce, farm size, herd size and farm yard manure disposal method used. Information collected on farm inputs included costs on shed construction, initial stock (animals), and equipment and utensils purchased (capital). Information on farm running costs (variable costs) consisted of farm expenses on labour, feeds, animal health, and routine farm services. Information on farm output was on milk and animal sale

## 3.4 Data Analysis

## 3.4.1 Standardization

All the information generated pertaining to production was standardized to conform to established rational economic measures for presentation as inputs used or outputs produced per anit of resource used. Land area in hectares, labour in man-hours, and capital in Uganda shillings avere considered as key farm resource inputs. Prior to computation, an appropriate monetary value avas estimated for every identified farm inputs and outputs. These values were assumed to be equivalent to the average market prices of the services or goods in question at the farm level. Actual values were obtained by asking the farmer how much he or she was offering, or was offered o purchase a given good or services. Alternatively, where a farmer had neither actual goods nor cervices purchased or sales made, the opportunity cost of such a good or service to the farmer mimself or herself was considered as its equivalent market value.

## **5.4.2 Selected Analytical Procedures**

The raw data from the study questionnaires, after being coded, were entered into a Dbase ile. It was then cleaned to detect any possible discrepancies and manipulated into a pro-written SAS programme for analysis. Three analytical procedures were used in handling the data: escriptive statistics, gross margin analysis and analysis of variance (ANOVA). Descriptive tatistics was used to compute figures to establish gross margin values while ANOVA was used to est whether mean gross margin values across the farm sampled were statistically different. tatistical significance was affixed at 95 percent level of confidence ( $\alpha$ <0.050). Gross margin was urther examined by modelling to identify factors (explanatory) that influenced its magnitude on individual study farms.

#### 3.4.2.1 Statistical Methods

Descriptive statistics involved constructing parameters of central tendency in the raw data in form of frequency distribution tables, mean values, modes, medians and percentages. This was supplemented by calculating measures of dispersion, variance and standard deviations. ANOVA was used to test whether figures obtained from different farms were different statistically.

## 3.4.2.2 Enterprise Gross Margin

Enterprise gross margin (EGM) analysis was the key economic analytical technique used in this study. Values were calculated for each farm by subtracting variable costs from gross income.

## **Enterprise Gross Income**

This was calculated by summing up the value of milk (yield\*price) produced in a period of time equivalent to one year (365 days) and annual animal sales on farms. The milk considered included amounts used to feed animals (mainly calves), household members, as gifts and actual sales. The change in animal inventory was assumed to be negligible because of the time the study considered (one year). A short run term consideration was taken. Animal products and by-products such skins, hides and draught power were excluded too in the estimates as none of the farmers had turned them into direct monetary values. It was also impossible to incorporate into enterprise gross income the monetary value of the manure produced by animals on a farm(s) as quantities and prices could not be meaningfully determined. Furthermore the investigator wanted to establish whether this system of dairy production would still be justifiable without farmers harvesting manure.

Furthermore manure is often used more as a benefit than a marketable farm product by most farmers Wange (1998).

#### Variable Costs

These were obtained by summing up estimated annual farm costs of inputs, which were routinely replenished. These included costs on veterinary inputs and services, animal feeds, transportation, plus costs incurred to pay for hired labour, both casual and permanent. Enterprise gross margin was then established by deducting variable costs from enterprise gross income. Lastly, EGM was weighed against important resource farm inputs, which are known to influence farm production. These included the land area used to produce fodder in hectares, the labour used in man-days, and animal(s) value, equipments and shed as capital invested by the farmer in Uganda Shillings (/-). Results were expressed as EGM/Hactare of land under fodder crops per lactating cow, EGM/man-day employed per lactating cow, EGM/capital investments per lactating cow respectively. The presentations gave the magnitude of a unit resource productivity for modeling.

#### 3.4.2.3 Modeling

An expanded functional form of the relationship Y=f(x) was used and the model developed took the following format:  $Y=B_0+B_1x_{1,n}+E$ .

Where: Y was dependant variable (out put),

xi.s are independent variables (inputs: 1,2,3...n),

B, are coefficients values which cause Y to change by one level unit,

Bo is constant (regression intercept) and

E is an error term which is possible in predicted Y values

Models were fitted by a forward/stepwise procedure in SAS programme using enterprise gross margin (EGM), enterprise gross margin per mean lactating cow (EGMC), enterprise gross margin per man-day per lactating cow (EGMMLD), and enterprise gross margin per captal per cow (EGMS) as individual dependent variables (Y). The explanatory variables  $(x_{1...a})$ ; location of the farm (zone), breed of the lactating animals kept (Breed), type of acaricide used (Acar), initial source of capital (Funso), farmers' educational levels (Educ), sex of the farm owner (Sex), access to off-farm sources of income (Occupt), breeding method (Mate), method of manure disposal (Manuse), markets for milk (Mkts), land tenure (Tenu), source of forage (Forg), prices of concentrates (Pcos), years of experience (Years), herd size (Hsize), family size (Fsize), farm size for livestock (Fstoc), total number of milking cows (Tdm), farm mean lactation length (Mlength), number of work hours (Dman), and mean milk yield (Mmean) were used in the models as independent variables.

36

#### **CHAPTER IV**

## **RESULTS OF DESCRIPTIVE ANALYSIS**

This chapter presents the results of descriptive statistics from the data generated by this tudy together with brief discussions and interpretations.

# **8.1. Farm Parameters**

## 6.1.1 Land Tenure

Three land tenure systems were recognized. These were mailo-land/freehold, lease-hold and customary. There were 21.1% (15/71) farms under the mailo-land/freehold system, 33.8% [24/71] on lease-hold and 45.1% (32/71) farms on customary system of land tenure. Almost half of the farmers (45.1%) still dwelt on plots of land that did not have land titles (customary ownership) According to Maxwell (1995) the majority of people in central Uganda do operate on pieces of land with unsecured titles because land ownership is still generally a contentious issue. Typically it is characterized by beruacry and high costs. These are curcumustancially limiting for the poor people. According to Maxwell (1995) the majority of people in central Uganda do operate on pieces of land with unsecured titles because land ownership is still generally a contentious issue. the poor people.

## 4.1.2 Farm Size

The size of the farm (excluding the cattle shed area) ranged from 0, where a farmer had no land at all, to 35 ha, with a mean of 4 ha ( $\pm$ 4.9). The farm sizes were generally small, and 52 (74.3%) of the 70 farmers who had recorded farm sizes had less than 4.1 ha; 11 farmers (15.7 %) had between 4.1 and 8 ha. Only 7 farmers (10%) had land area of more than 8 ha. Land area reserved for livestock (fodder) is presented as a percent of the total farm land area in Table 4-1. The table 4-1 shows that 15 (21.1%) of the 71 study farmers had less than 10% of their farmland under livestock, while 34 farmers (47.9%) had 11-30% of their farmland used for livestock. Only 22 farmers (31%) had more than 30% of their farmland reserved for livestock. This showed that the majority of farmers used only small proportions of their farmland for zero- grazing. The mean farm size obtained in this study is similar to findings of Sabiti (1994) of 1.25-12.5 ha for zero-grazing farmers in Kampala City peri-urban area. It is also in close agreement to the farm land size areas of zero-grazers in other parts of Uganda. For example 3.9 ha in Entebbe (Kalule-Sewali, 1994) and 5.4 ha in Ntungamo (Nalule, 1996). This mean farm size is also comparable to that established in Uganda nationally and other East African countries, that is, Uganda 5.2 ha (MAAIF, 1996), Kenya 4.6 ha (Omore, 1997) and Tanzania 6 ha (Ntengua and Steve, 1995).

The small size of total land area under livestock in this study is explained by the fact that crop production tends to be the dominant form of land use on smallholder farms in central and southern Uganda (MAAIF, 1996). The word smallness in this study is however relative. For example, in Java farms for peri-urban dairying households are only regarded to be small if their average sizes are less than 0.52 ha (Widodo et al., 1993).

% of land used	No. of farms	Percentage(%)	Cumulative %
for livestock			
<10	15	21.1	21.1
11-20	12	16.9	38.0
21-30	22	31.0	69.0
>30	22	31.0	100
Total	71	100

## 4.1.3 Herd Size

A total of 218 animals were found on the 71 selected study farms. These consisted of 77 lactating cows (35.5%), 17 dry cows(7.8%), 41 heifers (18.8%), 31 heifer calves (14.2%), 37 bull calves (17%) and 15 bulls (6.9%). The smallest units had one cow while the largest unit had a total of 10 animals. The mean and median of the herd size was 3 animals ( $\pm$ 1.5). Thirty-one farms (43.7%) had either 1 or 2 animals, while 20 farms (28.2%) had 3 animals. Eleven farms (15.5%)

had 4 animals and 9 farmers (12.9%) had five or more animals each. There were only 2 farmers (2.8%) that had single animals on their farms. These results show that the majority of farmers (69 farmers or 97.2%) kept more than one animal on their farms. The mean herd size (3) is similar to the established national herd size for zero-grazing enterprises in Uganda (MAAIF, 1996 and ILRI et al, 1996). Kalule-Sewali (1994) in Entebbe and Nalule (1996) in Ntugamo, also obtained the same value for zero-grazing herds they investigated. Widodo et al. (1993) found the mean herd size for zero-grazers in Java to be three. Similarly Omore (1997) found the modal herd size in Kenya (Kiambu District) to be three. The fact that very few farmers (2) had only single animals shows some progression and growth since, each farm initially started with one animal. This may however be a reflection of the small farm holders belief in animal numbers as a measure of livestock safety/economic success as suggested by Jahnke (Jahnke, 1982). It should also be noted that a herd of three animals: one cow, one heifer and calf is considered to be a rational animal family for zerograzers in Mpigi District (personal observation). It is also possible that some farmers have considered the economies of scale of production and are trying to increase the number of production units (cows). Indeed the keeping of only one animal under zero-grazing in Uganda has been found not to be cost-effective for certain farmers (MAAIF, 1996).

## 4.1.4 Animal Breeds

Both pure and crossed dairy animal breeds were encountered. Friesians and their crosses constituted the bulk of the stock, making up to 193 (86%) of the 218 total study animal population. Other breeds encountered included Jersey (one animal or 3.2%). Twenty-five animals

(11.5%) out of the 218 study population could not be categorized as their progeny was uncertain. Herds were either of purebred animals or of mixed breeds. Nineteen farms (26.8%) of the 71 study farms kept pure breeds (Friesian) while one farm kept a pure Jersey (1.4%). The remaining 51 farms (71.8%) had mixed breeds. These results show that the Friesian breed is the major contributor of genome (>86%) among the zero-grazed animals and that the majority of farms (71.8%) kept mixed breeds of animals. These results also show that very few farmers (28.2%) keep only one animal breed. This implies zero-grazers, like other smallholders, spread farm financial risks by diversifying the form of production even when dealing with seemingly similar enterprises.

The fact that certain animals' genealogy could not be established shows that farmers in the area attach very little (if any) importance to breed. Indiscriminate breeding of animals has also been rampant in Uganda (Mbuza, 1994). The dominance of the friesian breed and their crosses in the Ugandan dairy animals has been noted before, for example, MAIF (1988), MAAIF (1993), Kiconco (1995), Mbuza (1996), Sewali-Kalule (1994), Nalule (1996), ILRI *et al* (1996), MAAIF (1996) and Kinte (1998).

## 4.1.5 Herd Structure

## 4.1.5.1 Lactating Cows

The number of lactating cows per farm ranged from zero to four with a mean of 1.34 animals per farm. Three farms (4.2%) had no lactating animals while the majority (61 farms or 85.9%) had one lactating animal each. Seven farms (9.8%), however, had more than two lactating animals. Milk sales constitute the key daily source of farm incomes (ILRI *et al*, 1996). The presence of lactating animals on the majority of farms is therefore expected.

#### 4.1.5.2 Dry Cows

Dry cows were encountered on only 16 farms (23.5%), and 15 of these farms (94%) had single non-lactating animals each. The presence of a very small proportion of farms with dry cows is indicative of either shorter dry periods, extended lactation or synchronicity of lactation patterns for the study cows. Farmers mentioned that they at times had to shorten the dry period in order to maintain daily incomes if they had no alternative source of income to meet routine family sundry expenses.

## 4.1.5.3 Heifers and Bulls

Heifers were found on 37 farms (52%) and 33 of these farms with heifers (89.2%) had a single heifer each. Bulls were encountered on only 13 farms (18.3%), and they were largely kept in singles for breeding cows on the farm and neighborhood, as communal bulls. Two of the farms with bulls, however, had a pair of bulls each. These results show that only a very limited number of farmers maintained male animals on their farms up to breeding age. The zero grazers in the study area have easy access to artificial insemination services. The few bulls encountered were used as communal bulls and were located on farms on the fringes of the demarcated study area. The number of male animals in this study was very small compared to that of females. This was expected in zero-grazing systems. Since male animals are deliberately removed (culled) at an early age to avoid feeding them on expensive milk.

#### 4.1.5.4 Calves

Bull calves were found on 37 farms (52%) and 35 farmers (95%) had one bull calf each. The remaining 2 farms (5%) had two bull calves each. Heifer calves were present on 27 farms (38%). On these farms the number of calves ranged from 1 to 4 with 24 (88.9%) of the 27 farms with heifer calves having one calf each, and 2 farms (7.4%) having a pair of calves each. The remaining farm (3.7%) had a total of four heifer calves.

It is evident from these herd structures that female animals are dominant in the herds in terms of numbers, with the bulk of the herds being constituted by lactating cows and young heifers. This finding is similar to what was observed in 1996 by Uganda MAAIF workers on a nation-wide livestock systems' study (MAAIF, 1996).

## 4.2 Socio-economic Characteristics of Farmers

## 4.2.1 Sex

Of the 71 study farm owners 49 (69.0%) were females while 22 (31%) were males. There were therefore more female farmers than male ones. The dominance in the zero-grazing industry of female farmers has been previously reported in the LVC (Kalule-Sewali, 1994 and Kiconco, 1995). It is attributed to the fact that the industry is home based and fits in very well in the female gender roles as family managers. Also nation-wide, women in Uganda have shown a stronger presence in the zero-grazing system than men (MAAIF, 1996 and Mwebaze, 1994). Women in Uganda are also more likely to opt for landless forms of agricultural production such as zero-grazing as they

traditionally do not own land (Bigsten and Kayizzi, 1995; Mwebaze, 1994 and Kalule-Sewali, 1994). It is also likely that men get employed in the urban city nearby leaving women (wives) as farm operators.

## 4.2.2 Age

Age of the farm owner ranged from 26 to 76 years, with a mean of 45.7 ( $\pm$ 12) years. Table 4-2 shows the distribution of the ages of the farm owners at 10 year intervals. It should be noted that the majority (73.9% or 51/71) of farmers were of middle age, between 31 and 50 years. This age group, according to Murithi (1990), is the most productive age group in society, which often engaged in agriculture. The younger members of the society are often involved in career building activities (schooling) while the elderly lack the energy to engage in laborious manual labour. Both men and women past middle age were however observed in this study fully participating in zero-grazing without any obvious physical hindrance.

Age range(years)	No. of farmers	Percent(%)	Cumulative %
<31	2	2.9	2.9
31-40	33	47.8	50.7
41-50	18	26.1	76.8
51-60	12	17.4	94.2
>60	4	5.8	100
Totals	71	100	

## Table 4-2: Age Distribution Among Zero-grazing Farmers in Mpigi

Source: Author's Computation, 1998Source: Author's Computation, 1998Source: Author's Computation, 1998

## 4.2.3 Occupation

Eight (11.3%) of the 71 study farmers had zero-grazing as their sole source of earnings while 34 farmers (47.9%) combined zero-grazing with subsistence farming. The rest of the farmers (29 or 40.8%) had regular off-farm sources of income. The low level (11.8%) of farmers whose livelihood were entirely dependent on zero-grazing shows that very few people are engaged in zero-grazing as a possible sole source of farm income. According to Mbuza (1991) very few people specialise in dairy production in Uganda because returns to livestock as indicated by gross

margin calculation are generally low, which offers the farmers very little incentives to engage in it exclusively.

## 4.2.4 Marital Status

Fifty-five farmers (77.5%) out of the 71 study farmers had spouses while the rest (16 or 22.5%) were single. These results show that the majority of study farmers were married people. However, it should be noted that the number of single family heads was also relatively high. This is probably due to the fact that donor projects for zero-grazing animals in Uganda exercise a positive bias for the disadvantaged resource poor farmers (HPI, 1992). These are often single parent headed families such as widows, orphans and divorcees.

## 4.2.5 Educational Standards

None of the 71 study farmers was completely illiterate (that is, could neither read nor write). Those who had not attended formal educational institutions had informally acquired at least vernacular reading skills through religious institutions. Sixteen (22.5%) of the 71 sampled farmers had either informal or lower primary education, 22 farmers (31.0%) had full primary education and 33 farmers (46.5%) had above primary level education. Ten (30%) of the 33 farmers who had education levels above primary had acquired college training in various academic disciplines. Table 4-3 shows the farmers' educational level. It is evident that 55 farmers (77.5%) would easily communicate using English, which is Ugandas' official language. This finding is similar to that of Vanegas and Akwang (1992) who established that most dairy farmers in Uganda have basic formal

education: 29.7% having attained primary level education, 33.1% with secondary level education, and 32.2% with above secondary level education. It should however be noted that educational standards were too broadly categorized by Vanegas and Akwang.

# Table 4-3: Distribution of Educational Levels Among Zero-grazing Dairy Farmers in Mpigi District.

Educational standard	No. of farmers	Percentage(%)	Cumulative%
Informal and/or lower	16	22.5	22.5
primary			
Upper primary	22	31.0	53.5
Secondary	23	32.4	85.9
College	10	14.1	100.0

Source: Author's Computation, 1998

#### 4.2.6 Family Sizes

Of the 627 people found on the 71 study farms, 185 (29.5%) were adult female and 152 (24%) were adult males (14<age>66 years), 260 (42%) were children below 15 years of age, and 30 (4.8%) were old people, over 65 years of age. The mean family size was 8.8 ( $\pm$ 2.9) persons. The smallest families had only 4 members each while the largest family had 17 members. Majority

of families (84.5% or 60/71) had 6-11 members. Forty percent of the human population on the study farms was of very young people below 15 years of age. Majority of adults (53.9%) were females. These observations on zero grazing farmers' family are comparable to the national household survey report (MFEP, 1992). Families in the study, however, have more females than males contrary to the MAAIF findings (MAAIF, 1996). This difference is probably due to sample size effect. The sample size used in the MAAIF report was too small, only four (n=4) farms compared to seventy one (n=71) farms in this study.

## 4.2.7 Source of Funds

Forty-seven (66.2%) of the 71 study farmers had started their zero-grazing enterprises by using assistance from in-calf heifer donor agencies, 18 farmers (25.4%) had pooled personal funds while 2 farmers (7.0%) had acquired loans from livestock interest groups. Only one farmer (1.4%) had started by combining donor aid and pooled personal funds. These results showed that the majority of farmers (74.6%) were only able to start zero-grazing after acquiring some kind of financial assistance. It should also be noted that the majority (87%) of the 53 farmers that were assisted to start were beneficiaries of in-calf heifer donor agencies. Only 13% of the farmers had used means of assistance other than in-calf heifer donor agencies (loans). Small holder farmers in Uganda are generally poor and yet zero-grazing is an enterprise which requires high capital inputs. This explains why very few farmers (25.4%) had managed to start off without assistance.

48

## 4.2.8 Experience

The experience of farmers in the practice of zero-grazing ranged from 2 to 11 years, with a mean of 3.67 years ( $\pm$ 1.8). All the farmers however were found to have had prior experience with some kind of livestock before they embarked on zero-grazing. Fifteen (21.1%) of the 71 study farmers had kept animals for 24-30 months, 29 farmers (40.8%) for 31-48 months, 15 farmers (21.1%) for 49-60 months, and 12 farmers (16.8%) had animals for a time period exceeding 60 months.

#### 4.2.9 Milk Consumption

The volume of milk consumed per day by the family of the animal owner(s) ranged from 0 to 4*L*, with a mean of 2.42*L* (±0.94). This observed level of milk consumption is equivalent to 126 litres of milk per person per year on the farm(s). It is more than six times the national (24.5*L*-rural and 31.5*L*-urban consumers) level of milk consumption per capita in Uganda (Kabuye, 1994). The value obtained here is however comparable to the FAO (120.5*L*) recommended per capita milk consumption levels (FAO, 1989) and close to the level of milk consumption per capita in central Kenya (120*L*) (Sabiti, 1994). Non consumption of milk by zero-grazing households was also observed in Mpigi District in 1993 (Kalule-Sewali, 1994). Severe financial constraint was the reason advanced by farmers incriminated.

#### 4.3 Farm Production Parameters

## 4.3.1 Milk Yield

Milk production per farm ranged from 6L a day to 42L with a mean of 17.4L ( $\pm 9.4$ ). Expressed on a per mean lactating cow per farm, milk production ranged from 6L to 28L per day with a mean of 13.16L ( $\pm 4.3$ ). Milk production, expressed either on a farm level or as a function of the mean number of lactating animals, had therefore a median value which was less than the mean, implying that most farms with lactating cows were producing below the 13.16L daily production average established by the study. Similarly this mean-median profile can be interpreted to mean that few cows attained the mean production level quoted (13.16L).

Table 4-4 shows the distribution of mean milk yield per lactating cow on a farm basis. It should be noted from the table that 58 (81.7%) of the 71 study farms had cows with mean lactation yields of less than 16L per day. The range of milk production obtained in this study (6-24L/day) is generally higher than the 10-15L for pure breed friesian, 5-9L for crossbred/grades and 1-4L for indigenous cattle in Uganda reported between 1990-1993 (Vanegas and Akwang, 1992 and MAAIF, 1993). Despite the differences in range the average production (13.16L) from this study is close, within one standard deviation of the means given by other workers on dairy in Uganda. For example: 8-12L MAIF (1988), 12.5L MAAIF (1993), 10.62L Kalule-Sewali (1994), 13L Kiconco (1995), 7-15L, Bareeba (1995), 9-12L ILRI *et al* (1996), and 14L MAAIF (1996). It has however been noted in Uganda that among systems of dairy production, zero-grazing animals have the highest milk yields (MAAIF, 1996).

50

milk(L)/cow/day	No. Farms	percent(%)	accumm %

Totals	71	100	(

# Table 4-4: Milk Production Per Cow Per Day in Mpigi District

Source: Author's Computation, 1998

## 4.3.2 Lactation Length

The lactation length for milking cows per farm ranged from 300 days to 780 days, with a mean of 372 days (±83). These observations are well above the 305 days recommended lactation length for dairy animals. They are also beyond the 270-300 days stated by Sabiti (1994) and 325 days reported by ILRI *et al.* (1996) for dairy animals in Uganda. The observed lactation length is however comparable to those reported in the Kenya highlands (400-432 days) (Odima, 1994 and Omore, 1997). In these studies, prolonged lactations were attributed to delayed conception which led to large calving intervals. This has also been suggested to occur in the study area in animals

kept on poor nutrition (Sabiti, 1994). The lactation length observed here also compares very well with the calving interval (426 days) for dairy animals in Mpigi stated by Heinonen (MAAIF, 1993) when it is truncated by 60 days, the normal dry period given to lactating animals. Kiconco (1994), working in Mpigi, also encountered animals with calving intervals beyond 880 days which meant they had lactated for over 780 days, the upper limit of the observed lactation length in this study. Loss of the foetal calf (abortion) was also observed in the study. This led to farmers experiencing uninterrupted milk over consecutive pregnancies. This also stretched the lactation length. Some farmers reported that they deliberately extended the lactation period by delaying matings or by giving cows a shorter dry period. This was practised by farmers who wanted to maintain stable regular farm incomes from milk sales as long as it was possible. Table 4-5 shows the distribution of mean lactation length per study farm cumulatively. It should be noted that most study farms had their animals lactating for over 305 days, the normal recommended lactation period for dairy cows. Mean calving intervals for these farms would therefore inevitably extend beyond 13 months even if breeding was successful within 90 days post-partum.

(days)         <300       8       11.3       11.83         306-325       10       14.1       25.4         326-345       13       18.3       43.7         346-365       12       16.9       60.6         366-400       15       21.1       81.7         >400       13       18.3       100	mean lactation	length No.Farms	percent (%)	accum %

# Mpigi District, Uganda

Source: Author's Computation, 1998

# 4.3.3 Lactation Yield

The mean milk yields per cow in a lactation period ranged from 2,094L to 8,079L, with a mean of 4,465L ( $\pm$ 1,359). The median yield (4,487L) was higher than the mean (4,465L) but both measures of central tendency were quite close. This showed that majority of lactating cows

Table 4-5: Distribution of Lactation Length Among Zero grazed Animals in 71 Farms in

attained the mean lactation yield of 4,465L. The lactation yields observed in this study are comparable to the recommended optimum of 4,500-6,000L /lactation for Friesian animals. The yields are however higher than 1,664-3,630L range report on zero-grazing in different zones of Uganda (MAAIF, 1996). It should however be noted that these observed yields were attained from cattle in extended lactation phases at relatively low production levels. Longer lactation in low producing cows were also observed by Omore et al. (1994) in Kiambu District of Kenya. Poor reproductive management, sub-clinical diseases and limited availability of feed were advanced as possible causes for the observations made in lactation length. The mean lactation length of 372 days established in this study does not compare with that of the Kiambu study of 432 days. It is however apparent that milk yields in the study carried out in Kiambu District were lower (5.8/.) than those obtained in this study (13.16L). A compensatory kind of mechanism whereby cows which are poor yielder extend their lactation periods probably caused the differences obtained between these two studies. It is known that low yielding cows tend to compensate for their deficit by extending the lactation periods (Syrstad, 1993). The high milk yields attained by cows in this study show that it is possible for exotic dairy cattle to achieve their potential for milk production when conducive conditions are provided as suggested by Mwenya (1992). It should, however, be remembered that farmers who prolonged lactation lose a certain amount of milk and a proportion of calf crops in subsequent lactations. The opportunity cost involved in prolonging lactation must therefore be properly assessed by the farmer.

## 4.3.4 Annual Milk Output

The volume of milk produced per farm per year ranged from 2,094*L* to 15,150*L*, with a mean of 5,918.3*L* ( $\pm$ 3,226). The distribution of mean annual milk output by the farms is shown in Table 4-6.

Milk output(L)	No. Farms	percent(%)	accum %
<3100	10	14.1	14.1
3100-4099	17	23.9	38
4100-5099	12	16.9	54.9
5100-6099	8	11,1	66.2
6100-7099	6	8.5	74.6
>7099	17	25.4	100
Totals	71	100	

Table 4-6: Distribution of Annual Milk Output for 71 Farms in Mpigi District.

Source: Author's Computation, 1998

From the above, it can be seen that milk output from the farms was roughly evenly distributed, with 39 farms (54.9%) producing below the average, and 31 farms (45.1%) producing above the average. This pattern of milk production is expected since farmers were randomly selected and variations in genotype constitution and environmental conditions, including management, which influence annual milk yields (Mwenya, 1992) were also randomized on the farms.

#### 4.4 Prices of Essential Farm Inputs/outputs

## 4.4.1 Milk

The price of one litre of fresh milk ranged from 300 to 600 Uganda shillings, with a mean of 446/- (±76). The mean prices offered for milk were highest (503/-) for farmers selling their milk to nearby trading centres and lowest for farmers who sold their milk through vendors (389/-). Farmers selling milk to their neighbours received an intermediate milk price of 477/-. The milk prices registered in this study are similar to those observed in 1997 in Mukono (nearby) by Laker (1999). But higher than those reported in other parts of Uganda. For example Kalule-Sewali (1994) reported 400/- in Entebbe sub-district, Nalule (1996) 250/- for Ntungamo District, and Uganda MAAIF (1996), 295/- for Kabale, 276/- for Mbarara, 364/- for Kabarole and 300/- for Pallisa. Differences in prices in terms of place and locality are expected since prices are influenced by demand and supply forces. High prices are expected to prevail for milk in peri-urban environs as established in this study because of its high demand by the elite population in the city. Farmers would also obtain better prices by selling their milk directly to the consumers because middle men (Vendors) were cut out.

## 4.4.2 Veal Calves

Prices for veal calves aged 1-14 days ranged from 10,000 to 30,000 /-, with a mean of 25,000 /- ( $\pm$ 7,200). The length of time given to the veal calf to mature was determined by farmers on the basis of the colostral period allowed, and availability of market. All the veal calves were

bulls. Bulls normally prove to be costly to maintain as there are no milk replacers in Uganda. The farmers therefore decide to save on costs by selling the calves as veal. This is rational as it increases milk available for sale that would otherwise be consumed by calves. This is a direct attempt by farmers to increase their gross earnings through proper animal husbandry management.

#### 4.4.3 Heifers and Culled Cows

Prices of these animals ranged from 400,000 to 700,000/-, depending on the breed, size and age of the animal. Purebred animals (Friesians) generally fetched higher prices than cross or local breed animals. Reasons given for culling animals included poor milk production, diseases and old age. The prices offered to farmers for their heifers (400,000-700,0000/-) in this study is comparatively low because animals were sold at relatively young age of less than 6 months.

## 4.4.4 Animal Feeds

The cost prices for dairy meal (DM) ranged from 170/- to 360/- per Kg, with a mean (same as the mode) of 248/- ( $\pm$ 30). Eleven farms (15.5%) purchased DM at a cost price below 210/-, 58 (81.7%) utilized DM at a cost price beyond 210 but below 260/-. Only 2 farmers (2.8%) used DM costing over 260/-. The farmers attributed the differences in DM costs to difference in source and quality of the product. The cost prices for calf weaner ranged from 165 to 400/- with a mean of 264/- ( $\pm$ 65) per Kg.

### 4.5 Animal Husbandry Practices

### 4.5.1 Housing

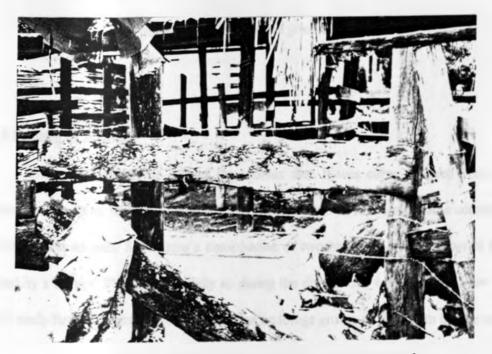

Animals were housed under permanent confinement in roofed but open sided sheds. The roofing materials used for constructing the sheds were either iron sheets or grass reinforced with polythene. Twenty-four farms (34%) had iron sheets while a majority of farms (66%) had the other types of roofing material. Floors were narrowly slatted and made of either bare compacted murram or concrete. Concrete floors were encountered on 52 farms (73.2%) while compacted murram floors were found on the remaining 19 farms (26.8%). Both calves and adult animals were housed side by side. Unweaned calves were however kept on raised calf crate(s) constructed within the dams' stall. Wooden feeder troughs were also constructed on the sides of the shed while water was provided in drums or sauce pans (Sufuria). Two separate below-ground level catchment areas were provided to trap the animals' urine and dung outside the shed. The majority of stall conformed to the building structures types for zero-grazing recommended by the Ministry of Agriculture, Animal Industry and Fisheries with minor variation. Plate 4-1(a,b,c) shows the types of stalls used.

Plate 4-1: Stalls Used to House Animals by Zero-grazers in Mpigi District

(a): Murram filled floor with an iron roof.

Note the flooded floor area indicated by arrow

(b): concrete floor with a papyrus covered iron roof.

(c): concrete floor with a grass thatched roof.

### 4.5.2 Feeding of Animals

Forage constituted the bulk of the animals' diet. It was either obtained from established pastures on the farm, from road reserve plots or purchased. Every farmer had a consistent source of feed for the animals. Sometimes a combination of two or all the three sources of forage was utilized by a farmer. This was especially so during the dry periods when pastures were scarce. Of the 71 study farms, 21 farms (29.6%) depended on forage grown on their farm units as established

leys, 10 farms (14.1%) were dependent on roadside cuttings, 4 farms (5 6%) used purchased forages, 24 farms (33.8%) used home grown pasture supplemented with roadside cuttings, and 9 farms (12.7%) used all possible sources of forage for their animals.

A number of forage types were used by the farmers to feed the animals. For routine animal feeding, all the farmers used nappier grass as a base bulk feed for their animals. Other forages used by farmers for feeding their animals included crop residues such as banana stems/peels and sweet potato vines. Banana peels were used on 43 farms (60.3%) while potato vines were utilized on 19 (26.8%) farms. In addition to these forages, some farmers fed their animals on garden weeds, kitchen left-overs, banana stems, crop tops, tree prunings, herbs and even waste paper. Most farmers semi-processed the forage by either wilting and/or chopping it before feeding it to the animals (Plate 4-2). The use of napier as a basal diet for zero-grazed animals in the tropics is known to be widespread (Abate *et al.* 1992). According to Nsubuga (1992) and Mwebaze (1994) farmers in Uganda prefer to feed their animals on nappier. This is so because nappier is hardy, high yielding and easy to harvest unlike other fodder crops in Uganda. It is also very palatable to cattle (Nsubuga, 1992).

Plate 4-2: Farmer Feeding Animals on Forage

(a) Fodder being processed by chopping and wilting

(b) animals feeding on fodder mixed with farm by-product (Banana stems)

High-energy feed used as concentrates on the farms included commercial/home made dairy meal, weaner calf pencils and brewers mash. Table 4-7 shows the quantity of dairy meal provided per animal. Dairy meal was used on all the 71 farms (100%) and it was fed exclusively to lactating animals with the exception of one farm, which fed dairy meal to all animals. The amount of dairy meal given per lactating animal ranged from 1.25 to 10 Kg per day with a mean of 4.5 Kg ( $\pm$ 1.9), 54.9% of the study farmers (more than half) gave their animals 4 kg or less dairy meal per day.

 Table 4-7: Quantity of Dairy Meal (DM) Provided to Lactating Cows Per Day Under Zero 

 grazing Systems in Mpigi District, Jan-Dec, 1997.

Kg DM	Frequency Percentage(%		6) Cumulative %		
2.0	17	23.9	23.9		
2.5	2	2.8	26.8		
3.0	4	5.6	32.4		
4.0	16	22.5	54.9

8.0	3	4.2	98.6		
10	1	1.4	100		
Totals	71	100			

Source: Author's Computation, 1998

Commercial calf weaner pencils (CWP) were used on 39 (55%) farms. The quantity of CWP provided to calves ranged from 5 to 320 kg (mean=71±56.5). The use of concentrate on the farm and the amount of concentrate given to individual animals was arbitrarily decided by the farm owner. The decision was said to be influenced by the availability and affordability of the concentrate, and productivity of animals.

### 4.5.3 Milking

Lactating animals were milked twice a day, early in the morning (between 6-8 a.m.) and in the afternoon (between 3 and 5 p.m.). Some farmers however reported that they sometimes milked their animals thrice in a day during early lactation when the animals produced a lot of milk. The method of milking used was hand milking by stripping by either the owner, a family member or sometimes a milk vendor. Milk let-down was induced by washing of the udder with lukewarm water and massaging the teats using milking salve. Commercial salve Salvo<sup>®</sup> was used on all the farms

### 4.5.4 Breeding

Farmers used both artificial and natural breeding methods. The natural method was used on 8 (11.3%) of the 71 farms where personal or communal bulls were used. Artificial insemination was used on 58 (81.7%) farms. The remaining 5 farms (7.1%) used a combination of both natural and artificial breeding. These results indicated that a majority of the farmers (81.7%) depended on artificial breeding services. This finding is similar to what was observed by Kiconco (1995),

MAAIF (1996), and ILRI *et al* (1996) in southern Uganda. It is however contrary to Nalule's (1996) findings which showed that in Ntungamo District all zero-grazers were dependent on the natural breeding method. The differences are likely to be due to the fact that Ntungamo is a typical rural setting which made the delivery of artificial insemination (AI) services impractical, as a result of poor infrastructure. This study area on the other hand has good infrastructure with good communication for delivering AI services. In this study, most farmers used the AI method because the method is economical for zero-grazers (MAAIF, 1996). This is largely because it is relatively cheaper to pay for AI services than meet the cost of maintaining a bull for small herds (ILRI *et al*, 1996).

### 4.5.5 Vector Control

Both sprays and pour-on acaricide preparations were used by the farmers to control ticks and flies on the farms. Pour-ons included Baytical<sub>(R)</sub> (Flurethrin) which was used on 36 (50.7%) of the 71 farms and Spoton<sup>(R)</sup> (Deltamethrin) which was used on 20 farms (28.2%). Decatex<sup>(R)</sup> (Deltamethrin), as a spray, was used to protect animals on 12 farms (17%). Three farmers (4.1%) used a combination of both sprays and pour-ons. For all the farms, all the animals would either be sprayed or dressed, with the exception of very young calves (<1 month). Results showed that pour-ons were preferred by most farmers (>78.9%). The MAAIF report also showed that a similar number (80%) of zero-grazers used pour-on in Uganda (MAAIF, 1996). Acaricide preparation in the form of pour-on are favoured by farmers in this study, probably because of their ease of application. In addition the use of pour-ons does not entail over-head costs in the form of purchasing a spray pump.

### 4.5.6 Labour Use

Both family and hired labour were used by the study farmers. Family labour was utilized by 70 farmers (98.6%) and the number of people contributing to family labour per farm ranged from 0 to 6, with a mean of 1.65 ( $\pm 0.78$ ) persons. Forty one percent Of those farms where family labour was used had only one member of the family who looked after livestock while 38 farmers (53%) had 2 members of the family who looked after livestock. Only 3 farms (6%) used 3 or more individuals to look after livestock. The total number of family members participating in zero-grazing was 108 persons (30%) out of 366 adult people living on farms.

Hired labour was either permanent or casual. The two forms of labour were used either concurrently or interchangeably. Casual labour was utilized by 44 farmers (62%), while permanent labour was utilised by 42 (59%) farmers. There was only one farm (1.41%) which depended exclusively on hired labour. The number of hired individuals per farm was restricted to one on 40 (93%) of the 44 farms using hired labour. The remaining 4 farms (7%) had two hired employees each. The number of hours required to carry out routine zero-grazing activities on farms ranged from 5.7 to 30.7 work hours per day with a mean of 16.5 ( $\pm$ 4.9) work hours. When the time required to carry out zero- grazing activities was expressed as a function of mean number of lactating cows on farms, it ranged from 2.4 to 29.7 work hours per cow with a mean 9.4 ( $\pm$  5) work hours per cow.

These results showed that the number of individuals involved in zero-grazing was small,

compared to the total number of available working people dwelling on the units, and that most of the farms utilised family labour. Also, the time required to carry out daily zero-grazing activities, both for the farm and on single animal basis, exceeded the normal man-day (8 work hours). This showed that at least two persons are required (full time) to provide labour on the farm(s) even when the farm has only one animal. The dependence on family labour observed was expected because the farmers were generally poor people who could not afford hired labour. Also, zerograzing is generally a part time occupation, with members of the family providing labour before they leave to tend to their main occupations.

The extra members of the families can also be considered as a potential reserve human resource maintained on the farm unit for providing extra work hours into zero-grazing in order to meet high labour requirements demanded by the system.

### 4.5.7 Marketing of Farm Produce

Milk and young bulls were the main sources of farm income. Milk alone contributed over 95.1% of the total farm income, leaving 4.9% as income from sale of animals. Milk was marketed either to neighbours, through vendors or delivered to nearby trading centres. Milk sold directly to the consumers by the farmers was either collected by the consumer or delivered to the consumers' residence by a family member. Some farmers also reported that they sometimes peddled milk in villages around their farms; this was especially so on week-end days. All the milk was sold in its natural fresh state and none of the farmers sold milk to formal milk handling institutions such as milk collecting centres. Morning and evening milk was marketed separately. The farmers would peddle milk over week-end days to utilize the extra labour provided by the school going children and partially so because civil servants who routinely consume milk on week days would be away on week-end holidays. This implies that the farmers had evolved a marketing strategy to suit prevailing local market conditions. The dominance of the informal Ugandan milk market has been long established. For example, according to the Uganda Dairy Master Plan Brief (1993), in 1990 over 70% of the milk produced in Uganda was handled by the informal dairy market sector (MAAIF, 1993). Farmers also mentioned that they were discouraged from using formal milk markets by the low prices offered to them, delayed payments and lack of transparency by the institutions' executives.

### 4.5.8 Disposal of Milk

Milk produced by the farms was used to feed calves, sold off to fetch income or\and used by the family as food (Figure 4-1). It was found that 22% of the milk produced was used on the farm to rear calves and\or as food for the family while the remaining 78% was marketed to fetch earnings. Some farmers did not market any milk (2/71) and others did not use any of the milk produced on their farms for food (1/71). Reasons advanced for this included low yields, which left producers with no surplus produce for sale. Some farmers also had to sell all the milk produced without leaving any for the family to meet scheduled financial obligations on the dairy unit. Of the volumes of milk sold, 41.2% was bought by people in the farm neighbourhood, 31% handled by vendors and 27.8% consumed in nearby trading centres or towns (Figure 4-2).

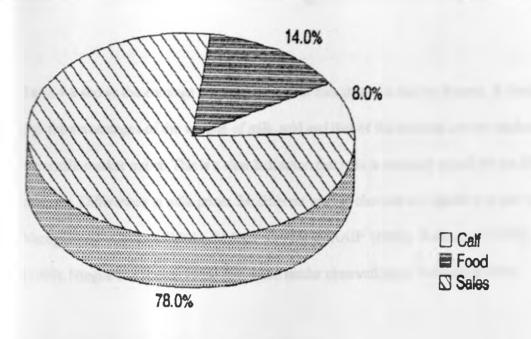

Figure 4-1: Distribution of Milk Among Disposal Methods

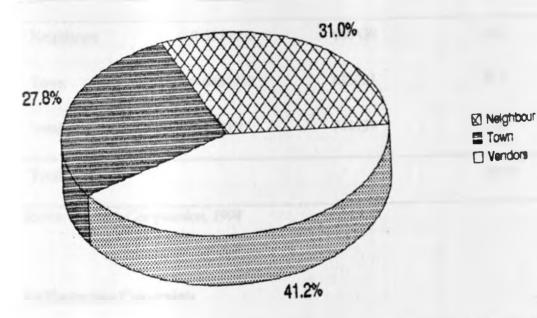

Figure 4-2: Distribution of Milk Among Market Channels

Table 4-8 shows the earnings from the volume of milk that was sold by farmers. It should be noted that the percentages of the volume of milk sold and that of the earnings are not equivalent for the same milk market outlet. This is a clear indication that milk is variously priced for the different milk channels. Differences in milk prices for different market channels in Uganda was also observed by Vanegas and Akwang (1991), MAAIF (1993), MAAIF (1996), ILRI *et al* (1996), and Laker (1999). Ntegua and Steve (1995) also made similar observations in Tanzania in 1994.

Channel	Range	Mean	Percent(%)
Neighbours	0-6559500	686420	30.1
Town	0-6483750	635021	30.1
Vendors	0-460380	748739	36.8

### **CHAPTER V**

### 5.0 RESULTS OF FINANCIAL ANALYSIS AND LINEAR REGRESSION

This chapter presents financial analysis and linear regressions, short discussions and interpretation of the results.

## 5.1 Enterprise Gross Income 5.1 Enterprise Gross Income 5.1 Enterprise Gross Income

This was constituted by considering the value of milk produced (total produce volume) and that of animal sales. Values ranged from 1,056,000/- to 9,024,000/-, with a mean of 1,314,292/-(±645,471) per farm per annum. According to a comparative analysis of dairy cattle management in different parts of Uganda (districts), mean gross incomes for zero-grazing enterprises in Uganda are 1,729,200/- for Kabale, 1,895,200/- for Mbarara, 1,398,240/- for Kabarole, and 742,800/- for Pallisa (MAAIF, 1996). With the exception of Pallisa District, all the equated figures are similar to the mean enterprise gross income obtained in this study.

Enterprise gross income (EGI), when examined using ANOVA was found to be significantly different between farmers with different educational levels (P=0.004), initial sources of capital (P=0.001) and access to off-farm sources of income (p=0.028). Farmers with higher educational levels had higher EGM than those with lower educational levels, possibly because education may make a farmer more receptive to advice (Sseruyange, 1994). Farmers who had started off with some form of assistance also had higher gross incomes compared to those who had started using their own savings, because farmers that started off on their own often could not

The table indicates that labour requirements (17.0%) is the problem biggest experienced by most farmers. This was expected as zero grazing is an enterprise which is labour intensive (Stotz, 1987; Dieckman, 1994; Widodo et, Ntengua and Steve, 1995). In addition within the study area manual work such as chopping grass, milking animals, vending milk are associated to gender, where females perceive it as being menial and too laborious. Women also often have a lot of odd jobs in their home. These include: caring for the family, cooking, home sanitation, washing and ironing clothes, and digging. With these set up the presence of animals in the homestead is obviously added work. Farmers in Uganda are also likely to complain as stall feeding cattle is relatively new and they are yet to become accustomed to it. The selling of milk is a common problem because (1) there are organised marketing systems (2) technical knowledge and facilities to preserve milk are lacking and (3) the high tropical temperatures also sours milk rapidly.

Other problems encountered by farmers can be explained by the fact that farmers are generally handicapped by lack of proper knowledge on how to manage animals in a stall. This is probably aggravated by the fact that extension services are inadequate too as reported by nine percent of the farmers. Manure disposal as a problem, although mentioned by only a few farmers, is likely to expand with increasing urbanisation. The significance of this finding is that in future manure disposal may be an important problem for farmers located close to the city. It is also interesting to note that Maxewell (1995) (using RRPA) did not identify manure disposal as one of the problems associated to presence of animal in kampala city (nearby). Here animals were allowed to roam and scavange freely.

78

afford exotic animals such as those imported by donor dairy projects. They instead purchased relatively cheaper animals locally, which turned out in the end to be poor milk producers. The volume of milk produced was small, thus gross income from its sales was also small. This directly lowered GI. Farmers with off-farm sources of income generally had a higher GI because they would easily afford to purchase inputs such as concentrates which influence animal production positively (Ofwona, 1994). These essential dairy inputs can raise milk production and raise GI directly (Murithi, 1990). Statistically significant differences in GI with respect to the farmer's educational standards observed in this study are contrary to what was reported by Widodo et al (1993) in households engaged in dairy in Java. The differences are due to the fact that farmers in Java are more experienced in managing zero-grazed animals, unlike in the study area where the industry is relatively new Enterprise gross income (EGI), when examined using ANOVA was found to be significantly different between farmers with different educational levels (P=0.004), initial sources of capital (P=0.001) and access to off-farm sources of income (p=0.028) Farmers with higher educational levels had higher EGM than those with lower educational levels, possibly because education may make a farmer more receptive to advice (Sseruyange, 1994). Farmers who had started off with some form of assistance also had higher gross incomes compared to those who had started using their own savings, because farmers that started off on their own often could not afford exotic animals such as those imported by donor dairy projects. They instead purchased relatively cheaper animals locally, which turned out in the end to be poor milk producers. The volume of milk produced was small, thus gross income from its sales was also small. This directly lowered GI. Farmers with off-farm sources of income generally had a higher GI because they

would easily afford to purchase inputs such as concentrates which influence animal production positively (Ofwona, 1994). These essential dairy inputs can raise milk production and raise GI directly (Murithi, 1990). Statistically significant differences in GI with respect to the farmer's educational standards observed in this study are contrary to what was reported by Widodo et al (1993) in households engaged in dairy in Java. The differences are due to the fact that farmers in Java are more experienced in managing zero-grazed animals, unlike in the study area where the industry is relatively new Enterprise gross income (EGI), when examined using ANOVA was found to be significantly different between farmers with different educational levels (P=0.004), initial sources of capital (P=0.001) and access to off-farm sources of income (p=0.028). Farmers with higher educational levels had higher EGM than those with lower educational levels, possibly because education may make a farmer more receptive to advice (Sseruyange, 1994). Farmers who had started off with some form of assistance also had higher gross incomes compared to those who had started using their own savings, because farmers that started off on their own often could not afford exotic animals such as those imported by donor dairy projects. They instead purchased relatively cheaper animals locally, which turned out in the end to be poor milk producers. The volume of milk produced was small, thus gross income from its sales was also small. This directly lowered GI. Farmers with off-farm sources of income generally had a higher GI because they would easily afford to purchase inputs such as concentrates which influence animal production positively (Ofwona, 1994). These essential dairy inputs can raise milk production and raise GI directly (Murithi, 1990). Statistically significant differences in GI with respect to the farmer's educational standards observed in this study are contrary to what was reported by Widodo et al

(1993) in households engaged in dairy in Java. The differences are due to the fact that farmers in Java are more experienced in managing zero-grazed animals, unlike in the study area where the industry is relatively new.

### 5.2 Variable Costs

Considered were costs on animal health, concentrates, feeds, labour, and routine farm services. Values ranged from 127,945/- to 2,985,278/- per farm per year, with a mean of 1,296,992/- (±723,562). Values for individual components of variable costs are as follows.

### 5.2.1. Animal Health Costs

Animal health costs ranged from 46,150/- to 864,000/- per farm per year, with a mean of 200,343/- (± 117,509). Variable costs considered included cost of milking salves, cleaning the pens, dry cow therapy, control of flies, control of ticks, vaccinations, deworming, control of theileriosis, plus costs of treating skin conditions, mastitis, tick borne diseases other than theileriosis, digestive disorders, reproductive diseases and any other non-specified diseases reportedly treated against on the study farms.

### 5.2.2. Cost of Feeds

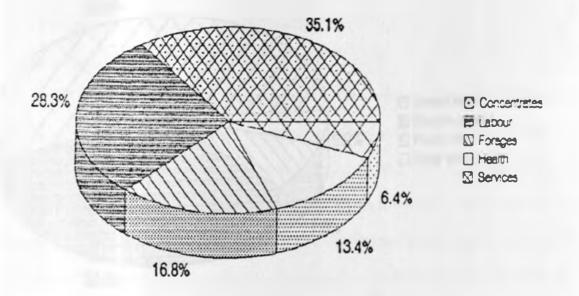

Forage costs included expenses on purchased forages which comprised of elephant grass, banana peelings, sweet potato vines, legumes, mineral licks and silage feed. These costs ranged from 4,000/- to 1,022,000/- per farm per year with a mean of 250,700/- (±249,070) per farm per year

### 5.2.3 Costs of Farm Services

These included costs of breeding, transport and membership to animal interest groups. These costs ranged from 8,000/- to 307,400/- per farm per year, with a mean of 96,100/-(±54,230) per farm per year.

### 5.2.4 Labour Costs

These were constituted by cost of hired labour which was either permanent or casual. The cost of hired labour ranged from 25,000/- to 895,000/- per farm per year, with a mean of 422,600/-  $(\pm 212,500)$ . About 59.8% of the labour costs were paid to permanent workers while 40 2% was taken by casual workers. The two forms of farm labour were therefore utilized about equally by farmers. Figure 5-2 shows the summary of farm costs in a form of a pie chart.

The median value (157,600/-) for the costs of animal feeds was however very small compared to the mean. This showed that the majority of farmers were spending less than the mean forage cost (250,700/-) per farm per year. Proportionately, banana peels were responsible for 56%, elephant (napier) grass 31%, potato vines took 7.8% while the remaining feed inputs took 5.2% of the total expenses (Figure 5-1).

Costs of concentrate feeds consisted of expenditure on dairy meal, calf weaner and brewers mash and ranged from 14,790/- to 1,790,000/- per farm per year with a mean of 523,500/- (±312,800) per farm per year. Dairy meal accounted for 89 percent, calf weaner 7 percent, and brewers mash 4 parcent of the total annual cost of concentrates used by the study farmers.

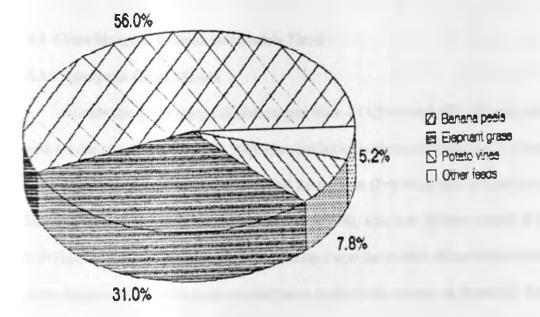

Figure 5-1: Distribution of Forage Variable Costs

Of these variable costs, 523,500/- (35.1%) was due to costs of concentrates, 422,600/- (28.3%) was due to labour costs, 250,700/- (16.8%) was due to cost of forage and supplements, 200,343/- (13.4%) was due animal health, and 96,100/- (6.4%) was due to costs of farm services. A comparatively similar pattern in the importance of farm variable costs in smallholders was reported by Murithi (1990) in Kenya. Using ANOVA the farm variable costs were established to be (only) significantly different by the type of forage source utilized by the farmer (P=0.007). Farmers producing their own forage had lower variable costs than those who used off-farm sources of forage. This was expected since farmers relying on off-farm sources of income had to spend more in order to cover costs for purchasing forage and paying for labour for bringing forage from outside the farm. These practices would inevitably raise their variable costs for running the unit.

### 5.3 Gross Margins Analysis and Models Fitted

### 5.3.1 Enterprise Gross Margin

Enterprise gross margin (EGM) ranged from -314,214/- to 5,600,026/- per farm per year, with a mean of 1,493,259/- (±752,900). The distribution is shown in Figure 5-1. It was found to be significantly associated with source of capital for the farm (P=0.001), type of acaricide used by the farmer (P=0.009), farmer's educational level (P=0.014), access to off-farm source of income (p= 0.005) and location of the farm (P=0.034). Farmers who had started off on their own had a smaller gross margin compared to those who had been assisted with animals or financially. Farmers who had off-farm income had a higher EGM than those who were either entirely dependent on the farm or simply practising subsistence farming. These factors are possibly explained by their effects on

GI. Farmers using Baytical<sup>(R)</sup> had EGM higher than those using Decatex<sup>(R)</sup> but there was no difference in the mean EGM between farmers using Baytical<sup>(R)</sup> and Spoton<sup>(R)</sup>. Also there was no observed mean difference in EGM between farmers using Spoton<sup>(R)</sup> and Decatex<sup>(R)</sup>. Lastly, farmers in zone I had higher mean EGM than those in zone II. This was so because farmers in Zone I generally kept pure bred animals which are higher milk yielders. This indirectly increases their EGM through their direct effect on GI.

It is interesting to note that some values of EGM are negative. Recently Laker (1998) working in Mukono District, Uganda, also observed negative EGM for dairy production systems. Jong and Zwart (1991) associated these negative EGM to the presence of forage costs in calculating farm variable costs as was the case in this study. But it is possible also that some farmers in this study had extended their spatial investing phase by injecting money into zero-grazing with little or no immediate financial returns. It is however interesting to note that despite the presence of some farms with negative EGM values, the overall mean EGM value for this study was positive. EGM values were not significantly associated with breed of lactating animals (P=0.081), source of forage on the farm (p=0.254), method of manure disposal used by the farmer (P=0.366), method used to breed animals (P=0.161), market channel used by the farmer (P=0.085), nor according to land tenure system (P=0.243). Among these factors, breed and source of forage are theoretically known to have direct bearing on EGM in dairy as they are both major components of its functions (GI and variable costs). In this study the effects of these important factors may have been concealed by farmers trying to increase their milk production at unnecessarily higher variable costs. This is suggestive of irrational resource use since the same production level would have been

achieved at a lower level of inputs use, and hence, variable costs. According to Aneja (1993) this occurs when the farmer(s) consider output as real farm profits.

When enterprise gross margins (EGM) were examined using linear regression, the final model with all variables left at significant levels of less than 0.050 include the volume of milk produced per lactating cow (p<0.001), milk prices (p< 0.001), mean number of lactating cows on the farm (p<0.001), prices of concentrates (p=0.091\*), growing forage on the farm (p<0.001), channel for marketing milk through vendors (p=0.013), and location of the farm (p=0.019). The prices for concentrate were left in the model although it had a probability value exceeding the critical (p=0.050) because it helped to stabilize the p values for other explanatory variables in the model. Altogether the factors explained over 89% ( $r^2$ =0.891) of the total variation in EGM on study farms. The prices of concentrates had a negative coefficient showing that EMG would be increased by reducing the prices. The remaining significant explanatory variables in the model had positive coefficients; therefore having/increasing their magnitude on the farm would increase the EMG upwards and positively. Table 5-1 shows details of the model for EGM.

### 5.3.2. Enterprise Gross Margin Per Lactating Cow

Enterprise gross margin per lactating cow (EGMC) ranged from -314,212/- to 3,023,800/-, with a mean of 1,001,83/- (±639,200). It was found to differ significantly, depending on the channel of marketing milk (P=0.004), the breed of lactating animals (P=0.018), location of the farm (P=0.020), farmer's access to off-farm income (P=0.021), and the initial source of capital for the farm (P=0.024).

Farmers selling milk directly to their neighbour had the highest EGMC, followed by those who took milk to nearby trading centres. Farmers selling their milk through vendors had the lowest mean EGMC. Farmers selling milk directly have higher EGMC because they made savings on farm variable costs by excluding vendor service costs. The higher EGMC here for pure breed animal (Friesian) can be explained by breed difference in levels of milk production which are directly proportionately related to EGMC through GI. Farmers who had started their units by way of assistance (i.e. donor cow or by taking loans) had a higher EGMC than those that had started using personal pooled resources due to differences in breed milk production potentials (see GI above). Farmers with access to off-farm income had a higher EGMC than those without due to input effects (see GI above). Farms located in zone I had a higher EGMC than those located outside it again due to breed effects (see GI above). It should be noted that probability (p) values for EGMC and EGM are about the same for similar explanatory variables, with EGM, however, having higher levels of significance. This can be interpreted to imply that the data collected in this study can be extrapolated to farms rather than to single animals. The modelling results for enterprise gross margins per lactating cow (EGMC) were similar to that of enterprise gross margin except TDM

had a negative coefficient and prices of concentrates were excluded (Figure 11). It should be noted that the model for EGMC explains only 65% ( $r^2$ =0.648) of the observed variation in EGMC. The results from this model compare well to those of Murithi (1990) who found that dairy production in the Kenya highlands was dependent on levels of milk yield, milk prices and the use of concentrate. EGM is dependent on growing forage on the farm probably because farmers make savings on labour required to bring or purchase fodder from outside the farm. In addition, farms using home grown forage are more likely to provide their animals with a consistent uniformly planned diet. This can in turn lead to better milk yield and raise GI which is directly proportionately related to EGM. The influence of market channel is due to the fact that vendors were offering the lowest prices for fresh milk but demanded no extra labour costs for marketing milk. This meant that the negative effects of low milk prices on GI were cancelled out by savings made on labour cost when the farmers sold milk at the farm. ### 5.3.3. Enterprise Gross Margin Per Man-day

Enterprise gross margins per man day (EGMMD) ranged from -421/- to 4,316/- per manday, with a mean of 1,408/- ( $\pm$ 1,010). It was found to be significantly different between farms with different market channels for farm produce (P=0.010), access to off-farm incomes (P=0.023), initial source of capital (P=0.024), and breed of lactating animals (P=0.036). Farmers selling their milk to neighbours had the largest EGMMD, followed by those who sold their milk through vendors. Farmers selling milk to nearby towns had the highest EGMMD. This trend in EGMMD with respect to the marketing channel is explained by the relative distance between the farm and place where milk was sold, as shown by no significant difference in EGMMD for farmers who sold milk to neighbours and vendors (p=0.81).

Farmers with off-farm sources of income had a higher EGMMD than farmers that did not have such job opportunities as farmers without other engagements would commit more time to zero-grazing from lack of alternatives. Farmers who had started off on their own without acquiring any form of assistance also had lower EGMMD than their counterparts who had started off by being assisted, probably because they were more careful lest they would fail to meet their financial obligations.

Lastly, farmers keeping cross bred animals had a higher mean EGMMD than those with pure bred animals. Exotic animals are more valuable than crosses in the study area. In addition they (animals) are considered to be more delicate, less resistant to adverse conditions, so need more care. The mean EGMMD obtained in this study is equivalent to a monthly wage of 36,608/- (1,408 /- per day\*26 days per month). This is lower than the minimum month wage (42,000/-) given to unskilled workers in Mpigi District. This value of EGMMD is also less than the daily wage (3,000/-) given to manual labourers (able-bodied porters employed at building sites) in the study area.

### 5.3.4. Enterprise Gross Margin Per Man-day Per Lactating Cow5

Enterprise gross margin per man day per lactating cow (EGMLD) ranged from -422/- to 4,898/, with a mean of 3265/- (±917) per cow per man-day. It was found to differ significantly between farms with different access to off-farm sources of income (p=0.001), the type of acancide used on the farm (P=0.003), location by zone (p=0.003), market channel for the farm produce (p=0.004), initial sources of capital (P=0.01), educational level of the farm owner (P=0.02), and the breed of lactating animal (P=0.029). Farmers having off-farm sources of income had higher EGMMLD than farmers without such incomes EGMMLD was highest for farmers using Decatex<sup>(R)</sup> followed by Spoton<sup>(R)</sup> and smallest for farmers using Baytical<sup>(R)</sup>. The mean EGMMLD for Spoton<sup>(R)</sup> and Baytical<sup>(R)</sup> were not significantly different from each other (p=0.76). Zone II farmers had a higher EGMMLD than zone I farmers. Farmers with lower educational levels had a smaller EGMMLD compared to those with high educational levels. Farmers selling their milk to neighbours had the largest EGMMD, followed by those who sold their milk through vendors. Farmers using off-farm sources of forage also had lower EGMMLD than farmers who were using farm grown forages. EGMMLD was higher for farmers who started off with some form of assistance than their counterparts that had started using only their own financial resources. Farmers

keeping cross bred animals also had a higher EGMMLD than those using pure bred exotic animals (Friesians). These results are similar to those of EGMMD except that the type of acaricide used, location of farm together with the educational standards of the farm owner are also included as significant explanatory variables. The use of acaracide as pour-on gave a big EGMMLD. Acaracides are applied less frequently (time and cost saving) when they are supplied as pour-on (ten or more days intervals for pour-ons (Baytical<sup>(R)</sup> or Spoton<sup>(R))</sup> compared to three or four days intervals for sprays (decatex<sup>(R)</sup>). The high EGMLD for zone II is a kind of confounder because the majority of farms in zone I have pure bred animals which demand extra labour inputs due to their higher milk yields and physiological delicacy. Differences in the EGMLD for educational levels can be explained by the fact that, with increasing education levels, farmers can cope better with new technologies by being able to deal with agricultural technical recommendations that are necessary to achieving technical efficiency (Aldermen, 1987). This can be envisaged as a saving on labour in terms of man-hour functions which is the case in this study. When modelled, variables left in the model at significant levels of less than 0.050 included size of the herd (p=0.001), the volume of milk produced per mean lactating cow per farm per day (p<0.001), mean number of lactating cows on the farm (p<0.021), growing forge on the farm (p<0.002), and starting the farm on aid (p<0.001), selling milk in the farm neighbourhood or through vendors (p<0.001). Total number of lactating animals had a negative coefficient. This showed that EGMMLD was negatively correlated to the mean number of lactating animals on the farm. This is so since more extra labour which is a component of variable costs is required as more animals are added to expand herd size and benefits of increased numbers are out outweighed by the cost of labour (Widodo et al., 1993).

All the remaining explanatory variables had positive relationships with the EGMMLD, their absence or decline would therefore reduce the magnitude of EGMMLD. The model fitted explained over 77% ( $r^2=0.773$ ) of the variation observed in the EGMMLD. This model was similar to that fitted for EGM except that it took into consideration the importance of herd size. Table 5-3 shows details of the model for EGMMLD (page 82).

### 5.3.5 Enterprise Gross Margin Per Capital Per Cow

Gross margin per capital per cow (EGMS) ranged from -0.14/- to 5.09/- per shilling, with a mean of 0.67/-, ( $\pm 0.77$ ) per shilling. The presence of some negative values for EGM showed that some farmers were receiving returns which were less than their invested capital. Enterprise gross margin per cow per capital was found to be significantly different between farmers according to the breed of the lactating animals kept (p=0.001), type of acaricide used on the farm (p=0.026), initial source of capital (p=0.031), and farmers' educational levels (p=0.048). The mean EGMS for farmers keeping cross bred animals was higher than that of farmers keeping pure bred animals. Enterprise gross margin per cow per capital was highest for farmers using Decatex<sup>(R)</sup> followed by those using Spoton<sup>(R)</sup> and smallest for the farmers who used Baytical<sup>(R)</sup>. There was a difference in mean EGMS between farmers using Decatex<sup>(R)</sup> and those using either Baytical<sup>(R)</sup> and Spoton<sup>(R)</sup>. There was however no difference in mean EGMS between farmers using Baytical<sup>(R)</sup> and Spoton<sup>(R)</sup> Farmers who started off without assistance also had a EGM values higher than farmers who had started off using their own resources and farmers with higher educational levels also had higher EGMS than those with lower educational levels. In this study all the statistically significant differences in EGMS with respect to a specific factor are explained by the effects of the factor on GI. When modelled, significant variables selected in the model included the volume of milk produced per mean lactating cows per farm per day (p<0.001), use of Decatex<sup>(R)</sup> (p=0.001), mean number of lactating cows on the farm (p=0.002), selling milk to neighbours (p=0.09\*) and keeping pure bred animals (p<0.001). Two factors, total mean number of lactating animals and keeping pure bred animals, had negative coefficients. They were therefore negatively correlated to EGMS.

This implied that EGMS would be increased by reducing the mean number of lactating animals on the farm. Similarly EGMS would be reduced by keeping non-pure bred animals. The model fitted explained 44% of the total variations observed in EGMS. This model is also similar to that of EGM with the exception that acaracide is identified as being important in determining EGMS. Table 5-4 shows details of the model fitted for EGMS.

#### 5.3.6 Enterprise gross margin per Hectare per cow

Enterprise gross margin per hectare per lactating cow (EGMLA) ranged from - 437,432/to 5,209,324/-, with a mean of 1,140,141/- (±947,439) per hectare. It was observed that the EGMLA figures were grossly very large because of the small farm sizes and farms with no land areas for growing animal fodder were actually left out to avoid getting infinite values. Gross margin per heactare per lactating cow when assessed was found not to be significantly different in all the study explanatory variables (p>0.050). Similar results were obtained by Widodo *et al.* (1993) in farming households in Java who concluded that land area - farm income relationships are not feasible for dairy systems where animals are stall-fed on forage obtained from outside the farm (Widodo *et al.*, 1993).

#### **CHAPTER VI**

#### CONCLUSIONS AND RECOMMENDATIONS

This chapter gives the main conclusions drawn from the results of this research and recommendation that can help researchers, policy makers and farmers to tackle some of the constraint identify by the study.

#### 6.1 Conclusions

#### **6.1.1 Economic Feasibility**

Results from this study have shown that, on average, farms have positive enterprise gross margins, meaning farmers are making profits. Zero grazing of cattle is therefore an economically viable venture in peri-urban parts of Mpigi. However, it is evident that there are wide variations in gross margins between farms, i.e some farms have small gross margins while others have very large gross margins. Majority of farms have gross margin close to zero too. The inference here is that most farmers get low returns.

The study shows these returns made by farmers could be increased by: (i) increasing the amount of milk produced per mean lactating cow per day, (ii) an increase in producer milk prices, (iii) a drop in the cost price of concentrate feeds; (iv) growing forage on the farm, (v) selling of milk directly to consumers at the farm; (vi) locating the farm closer to urban centres and (v) maintaining a smaller number of lactating animals on the farm.

The study also indicates that returns to labour or capital decline as the mean number of

6.0

lactating animals kept on the farm increases. Farmers with one lactating animal proved to perform better than those with two or more. In respect to this it can be concluded that economies of scale are not applicable with this study herd size. Similarly, returns on for zero-grazing by farmers could not be meaningfully interpreted. Farms that had no or very little land reserved for animal fodder production manifested infinitely large gross margin per unit land. Land, as a factor of production, is therefore not a key constraint among zero grazing farmers in peri-urban areas if free fodder can be got from outside and ferried in, using relatively cheap labour.

The study revealed too that returns to the farmers' capital are higher when grade or crossed animals are kept. It was thus concluded that farmers could improve their return to capital by initially starting zero grazing with grade or crossed animals other than going straight for pure exotic dairy animals.

### **6.1.2 Production Constraints**

Labour requirements on farms is the most important constraint limiting production for most zero grazing farmers. The second major constraint farmers faced was lack of markets for their produce (milk). This problem was followed by the problem of livestock diseases, high cost of farm inputs especially dairy concentrates, low milk yields from some of the animals, periodic shortages of fodder on farms, inadequacy of veterinary extension services and presence of animals with poor reproductive performance. There is also water shortages, lack of credit facilities, and insecurity of animals on some farm. In areas which have become urbanised manure disposal is also cropping up as a problem.

Labour and markets for milk being the most limiting factors must be addressed foremost by farmers. Solutions to other problems should then follow according to order of importance with manure disposal being attended to last. However for farms located in fully urbanized areas manure removal must be immediate to minimize pollution.

#### 6.1.3 Variable Cost Components

The costs met by farmers in providing daily concentrate feeds is the largest component of farm variable costs. This is followed by the cost of hired labour on the farm, the cost of fodder, costs incurred to prevent or treat animal diseases and the cost for routine farm services. It can be concluded from these findings that peri-urban farmers in Mpigi district endeavour to feed high energy feeds to their lactating animals (cows) to improve production. Hired labour is also considered important and is utilized by farmers.

#### 6.2 Recommendations

It is apparent from this study that the majority of zero grazing farmers in peri-urban parts of Mpigi make minimal profits, and receive poor returns on their labour and invested capital. Mobilization must therefore be carried out for these farmers so that they are sensitized about their poor production status. This can be achieved by conducting seminars, workshops and shows for farmers during which production can be discussed. Emphasis must also be placed on how the farmers can produce optimally, say by reducing production expenses while raising their gross incomes. Within the scope of this study this can be achieved through improved management,

particularly that which aims at increasing milk yield by individual animals on daily basis Areas, which can be exploited, include:

(1) Nutrition: each animal on the farm must be provided with sufficient fodder with concentrate added for lactating animals according to their production potential and physiological demands. Water must be provided ad libitum

(2) Breeding: every farmer must identify and cull cows on the farm that are poor milkers. Superior sires and dams must be selected or sought to serve as replacement stock.

(3) Record keeping: this must be instituted by farmers so that farm production and animal reproductive events are closely recorded and monitored.

(4) Animal housing: Housing must be examined and as most farmers have their animals in iron roofed shade which constantly heat up the animal(s) during day time. Research must be undertaken to established whether such roof types are not acting detrimentally on animal's productivity.

(5) Labour utilisation: since labour contributes a big component of farm expenses, there is need to re-organise labour. Hired labour must be restricted in favour of family labour. Farmers should be encouraged to met all labour requirements using family labour. Practically, this can be achieved on the farm by committing more working hours to an enterprise and using family labour where and/or whenever it is available. For example, before and after school, children can harvest, ferry and chop fodder, fetch water, milk animals and deliver milk to its consumer. Farmers must also be encouraged to produce their own fodder since most of the hired labour is used to collect fodder. Farmers with no access to nearby free road-side forages or any farm by products, nor land

for planting forage must acquire land to produce their own fodder. This can be either by saving or taking loans.

(6) Capital utilisation: in order to obtain maximum benefits from their capital farmers starting zero-grazing must initially consider the rearing of cross breeds or grade cattle instead of pure bred animals. Farmers already having the local breed types of cattle must start up-grading their animals. An effective artificial insemination (AI) system should also be established to deliver timely services to farmers effectively. In areas far from the AI centres elite breeding bulls must be availed to the farmers to reduce the current practice of using untested sires.

(7) Produce selling: milk is a highly perishable farm product, which must be sold at once else it goes sour and becomes wasted. To limit possible losses the farmers with market uncertainty must be organized into groups and provision make for them to acquire milk coolers. Additional farmers should also be encouraged to turn milk into finished dairy products to add value to the product so that the farmer's earnings increase. Farmers must also be equipped with knowledge of salvaging spoiled milk and making it into sellable products such as Ghee.

Since this study revealed that, economies of scales are not being taken advantage of, farmers must be encouraged to reduce their herds by culling out animals which are inferior in production. For urbanised areas where manure has become a nuisance, biogas technology must be introduced so that biogas is produced to supplement household fuel supplies.

Within the extremes of these recommendations and study limitation it should be remembered that zero-grazing has numerous advantages which are not easily quantifiable into monetary terms. These included the biological values of manure say: on crops, as domestic fuel, construction material and chemotherapeutic agents. Smallholder farmers also generally lack technical guidance, which limits their chances of engaging in non-traditional agricultural production systems. For this category of farmers zero grazing would serve as the best alternative even if profits are minimal. The same would apply for farmers in highly urbanized areas without enough land resources of their own. Zero grazing would also be recommended in peri-urban areas of Mpigi district where free road-side fodder is abundant. For house wives whose main work is to tend to household chores zero grazing would also be a good part time occupation which is gender sensitive.

APPENDIX:1

#### QUESTIONNAIRE

ECONOMICS OF PERI-URBAN ZERO-GRAZING IN UGANDA: THE CASE OF MPIGI DISTRICT

1.	Study	area
----	-------	------

County (LC4)	
Sub-county (LC3)	
Parish (LC2)	
Village (LC1)	
Date	
Interviewer	

2. Respondent

1

(Use tick)

Names	Sex	Age (Yrs)	Relationship with the farm owner					
			Wife	Son	Daughter	Employee	other	

For other, explain (briefly)

#### 3. Information on farm owner

(Use tick)

Names	Sex	Age	Marital status			000	Occupation			Education					
			1	2	3	4	1	2	3	4	1	2	3	4	5

Codes for 3.0;

<pre>(i) Marital status; (ii) Occupation;</pre>	1: Married, 2: Single, 3: Widow, 4: Widower 1: Zero-grazer only, 2: Subsistence, 3: Farm
employed (iii) Education;	1: None, 2: Primary, 3: Secondary, 4: College,
Explain	5:

4.0 Household information

Age group (Years)	Below	15	15-65		Above 6	5	Total	
Sex	F	M	F	м	F	м	F	M
Number								

Codes; F:Female, M: Male

#### 5.0 Information on livestock

# 5.1 What kind of livestock do you have?

Species	Cattle	Goats	Sheep	Pigs	Rabbits	Poultry	other specify
Numbers							

## 5.2 How were the animals obtained?

(Use tick)

	Species	Personal Funds	Obtained on loan	Project donation	other specify
1	Cattle				
2	Goats				
3	Sheep				
4	Pig				
5	Rabbits				
6	Poultry				
7	Others				

5.3 For how long have you been keeping cattle (Number of months);

#### 5.4 For cattle, what is the herd structure?

Туре	Herd	C	Cows	Heifer	Bulls	c	alves
		Lactating	Dry			F	м
Number							

112

(give numbers)		Friesian	Jersey	Crosses	Local	Unknown
COWS	Lactating					
	Dry					
	Bulls					
	Heifers			-		
Calves	Female					
	Male					
	Totals					

# 5.5 What are the breeds of animals (cattle) kept?

## 6.0 Land utilization

6.1 Farm size and tenure

	На	Tenure 1, 2, 3	Comments
Land owned			
Land rented			
Land Hired out			
Total Land used			

Codes for Tenure; 1: Free-hold/mailo, 2: leasehold, 3:Customary

#### 6.2 How is the land used

	Use	На	Comment
1	Producing Animal Fodder		
2	Crop farming		
3	Horticulture		
4	Woods/Forestry		
5	Fallowing		

\*\*\*Comment whether crop is in pure stands or intercropped?

## 7.0 Labour aspects

# 7.1 Who takes care of the cattle which are zero-grazed?

(give numbers)

Labour source/farm	Women	Men	Children	Total
Family members				
Hired workers				
Totals				

#### 7.2 For hired worker/labour indicate how payment is done.

(Use tick)

Labour form	Cash	Milk	Food	Accommodatio	other specify
Casual					
Permanent					
Cost for month*					

\* Applicable for permanent labour only

Extra information:

# 7.3 How much was spent (cash/material) to pay for labour in 1996?

Form of labour	as Cash	as milk	as accommodation	as food	other specify	Total
Casual						
Permanent						
Totals						

	Activity	Sources 1, 2	No. of individuals	Time spent (hrs)
1	Supervision			
2	Milking			
3	Collecting forage			
4	Fetching water (for animals)			
5	Cleaning shed			
6	Applying acaricide			
7	Watering/feed ing animals			_
B	Marketing milk			
9	Others			
10	Totals			

# 7.4 Who normally provide the following services?

Codes for 7.4 (source); 1: Family members, 2: Hired workers

# 7.5 Expense on specific labour related inputs, 1996

	1990 B B B B B B B B B B B B B B B B B B	Category			
	Activity/Service				Amount
		Family	Casual	Permanent	
1	Supplying fodder				
2	Weeding fodder				
3	Transport				
4	Milking animals				
5	Supplying water (Animals)				
6	Marketing milk				
7	Repairing cattle shed				
8	Others specify				

8.0 Animal husbandry aspects, 1996

8.1 Drugs and chemicals (costs)

	Item	Use (Yes or No)	Amount spent	Comments
1	Milking salve		-	
2	Dry cow therapy			
3	Dewormers		-	
4	Detergents/soap			
5	Acaricide			
6	Fly repellant		-	
7				
8	Others			

# 8.2 Type of acaracide used

Acaraci de	Bayticl	spoton	decatex	supona	Greases	Others	none
Numbers							

# 8.3 Treatments (costs)

	Disorder	Use (Yes or No)	Amount expense	Comments
1	Vaccinations			
2	Mastitis			
3	Gastro-intestinal disorder			
4	Reproductive disorder			
5	Skin/hoof disorder			
6	East Coast fever			
7	Other tick borne diseases			
8	Others unidentifiable			
	Total costs			

9.0 Animal nutrition

9.1 What types of feeds are utilized on the farm?

	Feed	Source 1, 2, 3	A11	Animal fed lactating	Heifer	Calves
1	Napier					
2	Banana peels					
3	Potato vine					
4	Silage					
5	Tree Prunings					
6	Garden weeds					
7	Mineral licks					
8	Legumes					
9	Dairy meal					
10	Weaners					
11	Brewers mash					
12	Others specify					

Codes for 9.1 (Source); 1: Farm, 2: purchased, 3: collected free

9.2 Expenses on feeds, 1996

9.2.1 Forages

	Feed	Expenses incurred	Comments
1	Napier/legumes		
2	Banana peels		
3	Potato vines		
4	Silage		
5	Others		
	Total		

9.2.2. Concentrates

	Feed	Expense incurred	Comments
1	Dairy meal		
2	Calf weaner		
3	Brewers mash		
	Total		

9.2.3 Supplements

	Supplements	Expense incurred	Comments
1	Minerals		
2	Salts		
3	Others		
	Total		

10.0 Products from animals

10.1 Uses

(use codes given below)

	Output	Use 1, 2, 3	Comments
1	Manure		
2	Milk		
3	Animals		
4	Skins and hides		
5	Draughter power		
6	Others		

Codes for 10.1 (use); 1: Home, 2: Sold, 3: Given away free

10.2 Production levels ( apply to animals with completed lactation)

(use farm record book)

Animal	Breeds 1, 2	Daily milk Production	Lactation Length (L)	Lactation Yield (L)	Parity
1					
2					
3					
4					

Codes for 10.2 (Breeds); 1: Friesian, 2: Others

10.3 Milk used to feed calves

Calf	Sex M or F	As colostrum (Litres)	Saleable milk (litres)	Duration of feeding allowed
1				
2				
3				

Code for 10.3 sex; M:Male, F:Female

# 10.4 Milk used by the family

Amount	consumed	per	day	Duration	Comments

# 10.5 Milk outlets (markets)

(use Tick)

Market	Neighbours	Vendors	Nearby town	comments
All surplus				
Shares*				
Milk price				

 Shares; Average quantity of milk channel through the market (percentage)

## 11.0 Farm services, 1996

	Services	Expense incurred	Comments
1	Breeding		
2	Transport		
3	Memberships		
4	Others		
	Total		

	Item	Numbers	Cost incurred	Year	condition 1,2,3,4
1	Animal(s)				
2	Animal shed construction				
3	Bike(s) \Vehicles				
4	Wheelbarrow(s)				
5	Drum(s)/Tank(s)				
6	Water trough(s)				
7	Feed trough(s)				
8	Hoes, panga, slasher(s)				
9	Water container(s)				
10	Spray pump(s)				
11					
12					
13					
	Total				

11.1 Farm animals, equipments and utensils used to operate farm

Codes for 11 (condition); 1:good, 2:worn out, 3:replaced, 4:lost

.

12 General questions/comments

12.1 Constrain

	Problem encountered by farmer	Ranking				
1	Shortage of forage					
2	Cost of inputs					
3	Animal diseases					
4	Marketing of milk					
5	Manure disposal					
6	Low milk production					
7	Poor extension services					
8	Reproductive failure					
9	Shortage of water					
10	Shortage of inputs					
11	Death of animals					
12	Poor credit facilities					
13	Others					
	Total					

## 12.2 Recommendations

	Recommendation/outlook	No or yes
1	Expand by adding more animals	
2	To discontinue with enterprise	
3	Change system of production	
4	Change the breed of animal used	
5		
6		
7		
	Total	

APPENDIX:2 SUMMARY OF INFORMATION COLLECTED GENERATED BY THE STUDY

- (i) Codes
- 1. Sex Sex of the farmer (1: Female, 0: Male)
- Occupt Type of farmer's livelihood (0: Zero-grazing 1: Subsistence, 2: Regular off-farm work)
- 3. Farmsize Number of people in the family of farm owner
- 4. Child Number of family members with ages below 15 years
- 5. AdultF Female family members with ages between 15-65 years
- 6. AdultM Male family members with ages between 15-65 years
- 7. Aged Number of family members with ages below 65 years
- Funso
   Source of fund used to start zero-grazing (1: palled personal savings, 2: Loan, 3: Project 4: Combinations)
- 9. Comm Year when farm was established (zero-grazing unit)
- 10. Hsize Number of animals on farm (cattle only)
- 11. Dry Number of non-lactating cows on the farm
- 12. Heif Number of young female animals on farm (6 months-first calving)
- 13. Bull Number of male animals above 6 months on the farm
- 14. Hcalf Number of female calves (< 6 month) on the farm
- 15. Mcalf Number of male calves (< 6 month) on the farm
- 16. Tenu Type of tenure system on units which the farmer operates (1: Mailo/free hold, 2: Lease 3:, Customary)
- 17. Farsize Farm size (Ha)
- 18. Farsto Farm area used for producing fodder for zero-grazed animals (Ha)
- 19. Lfarm Number of family members actively engaging in zero-grazing
- 20. Lemplo Number of hired worker on the farm
- 21. Costcas Amount of money paid to casual workers by the farmers in 1996 (Uganda Shillings (Ush.))
- 22. Costper Amount of money (Ush.) paid to permanent worker in 1996
- 23. TFo Time (hours) spent by workers in 1996 to provide fodder to animals (cutting, collecting and carrying)
- 24. Tma Time (hours) spent on marketing milking

- 25. Tmi Time (hours) spent on milking animal(s)
- 26. TSH Time (hours) spent cleaning cattle shed(s)
- 27. TSU Time (hours) spent by farm owner on supervision and helping on zero grazing unit
- 28. Twas Time (hours) spent doing other farm activities
- 29. Twat2 Time spent (hours) on collecting water
- 30. Cosalvo Cost of milking salve
- 31. Cosdct Cost of dry cow therapy tubes
- 32. Cosworm Cost of dewormers
- 33. Costik Cost of acaracide
- 34. Costly Cost of fly repellents
- 35. Cosvac Cost for vaccination
- 36. Mast Expenses to treat mastitis
- 37. Scour Expenses on gastro intestinal disorder/diseases
- 38. Ugod Expenses on reproductive disorders/diseases
- 39. ECF Expenses for treating East Coast Fever
- 40. Tbd Expenses for treating tickborne disease beside East Coast Fever
- 41. ODD Expenses on disease condition that were not clearly identifiable
- 42. Acar Type of acaracide used by the farm (1: Baytical 2: Spoton 3: Decatex 4: combinations)
- 43. Farso Source of forage (1: Home grown 2: Purchased)
- 44. Cosfor Cost of forage (purchased)
- 45. Silo Cost of making/buying silage
- 46. Esfed Cost of buying brewers mash, maize stores
- 47. Cosbp Cost of buying banana peels
- 48. Cospv Cost of buying potato vines
- 49. Coscy Cost of concentrates in 365 day
- 50. Wcost Cost of calf weaner
- 51. Cosmisa Cost of minerals licks/salts
- 52. Manuse Use of manure on the farm (1: Crop fertilizer, 2: Thrown away, 3: Sold 4: others)
- 53. Mmean Volume of milk produce by farm per day
- 54. Lyld Volume of milk produced by cow(s) per lactation
- 55. Llength Accumulated lactation length for cows on the farm

56. Mhome Volume of milk consumed by family per day

- 57. Mate Method of breeding used by the farm (1: Bull, 2: Artificial Insemination, 3: 1 & 2)
- 58. Costran Cost expenses for the farm in form of transport
- 59. Cosmem Cost expenses for the farm in form of membership fee to animal interest groups/subscription
- 60. Capcow Amount of money for purchasing initial farm stock
- 61. Capunit Amount of money for shed construction
- 62. Year Number of years animal(s), item(s), shed(s), equipment(s) since they were purchased
- 63. Bike Cost of bicycles, wheelbarrow, vehicle
- 64. Drum Cost of water drum(s), tank(s)
- 65. Drinka Cost of water trough
- 66. Feda Cost of feed trough
- 67. Oimp Cost of panga, hoes, slasher etc
- 68. Jeca Cost of water containers/carriers
- 69. Pump Cost of spray pump(s)
- 70. Mprice Milk prices
- 71. Mllength Mean lactation length on farm
- 72. Incsa Income from sale of animals
- 73. Tdm Number of lactating animals on the farm
- 74. GI Farm gross income
- 75. Newvcto Farm variable costs (total)
- 76. Fgmnew Farm gross margin
- 77. Newfgmc Farm gross margin per cow on farm
- 78. Mo Value of milk produced by farm in 1996.
- 79. Asee Farm identity (code)
- 80. Age Age of the farm owner
- 81 Dmanhrs Hours works utilised by farm in 1996
- 82. Dmanhrs Hours works/cow utilised by farm in 1996
- 83. VETS Poor extension services
- 84. Market Lack of markets for farm produce
- 85. Labour Labour shortages86. Repre Poor reproctive performance

- 86. Repre Poor reproctive performance
- 87. Thefty Livestock thefty
- 88. Milk Low milk yield
- 89. Forge Shortages of fodder
- 90. Manure Manure disposal
- 91. Inputs farm inputs
- 92. Credit Lack of credit facilities
- 93. Disease Livestock disease
- 94. Water Water shortages
- 95. M Factor(s) not mentioned

APPENDIX 3: Summary of mean values for parameters used in establishing gross margin

Value in Uganda Shillings

Input or output	Zone 1	Zone 2	Over all
A: Feeds	(n = 30)	(n = 41)	average
1. Concentrates	511,200	540,400	523,500
2. Forages\supplements	246,500	253,700	250,700
B: Hired labour		2007.00	2007.00
1. Casual	75,230	33,670	51,230
2. Permanent	126,900	200,400	169,500
C: Farm services			
1. Breeding	38,720	33,080	41,100
2. Transport	42,930	40,190	41,350
3. Memberships	30,100	12,780	20,100
D: Health related			
1. Acaracides	78,060	110,900	96,990
2. Salves	8,630	7,186	7,796
3. Fly repellants	2,943	2,402	2,631.0
4. Detergents/soap	6,185	6,525	6,381.3
5. Dry cow therapy	3,450	6,732	5,345.1
6. Mastitis (D)	16,950	4,834	9,911.3
7. Reproductive disorders (D)	101,800	4,073	6,654
8. Gastro-intestinal disorders (D)	2,587	842	1,578.9
9. Tick-borne diseases (D)	15,030	10,320	12,310
10. Hoof and skin (D)	1,919	2,283	1 2,086
11. Non-specified disorder (D)	9,967	18,850	15,100
12. Dewormers	13,190	16,200	14,930
13. Vaccinations	2,167	. 3,866	3,147.9
14. East coast fever	7,667	20,870	15,290
E: Gross income			1
1. Milk value (Ush.)	2,304,300	2,995,000	2,649,000
2. Sale of livestock (Ush.)		138,900	403,900
F: Capital items			T
1. Animals	1,157,000	1,074,000	1,109,000
2. Shed construction	312,000	265,500	295,200
3. Spray pumps	7,533	8,854	8,296
4. Bike/vehicle/wneel barrow	31,700	43,760	39,660
5. Feeder troughs	8,756.7	11,730	10,490
6. Drinker troughs	12,380	14,320	13,500
7. Drums/tank	10,330	15,500	13,320
8. Water carriers	6,400	7,178	6,849
9. Milking buckets	4,960	9,327	7,439.4
10. Other implements (pangas, hoes,	19,770	19,090	19,370
G: Work hours (daily analysis)			

1. Milking	1.1	0.96	1
2. Collecting forage	4.8	5.9	5.4
3. Marketing milking	1.2	1.4	1.3
4. Cleaning sheds	1.5	1.5	1.6
5. Supervision/feeding/watering	3.9	3.5	3.7
6. Collecting water	1.9	2.3	2.1
7. Other work activities	2.1	2.4	2.2
H: Production factors			
<ol> <li>Farm area reserved for animals fodder (Ha)</li> </ol>	1.5	6.1	3.52
2. No. animal per farm (herdsize)	2.5	3.5	3.1
3. No. of lactating animal per farm	1.2	1.4	1.3
Parameter			
1. Gross Margin			
2. Gross Margin/lactating cow			
3.Gross Margin/capital			
4.Gross Margin/hactare of land
