(i)

This research paper is my original work and has not been submitted for examination in any other university.

Violet Sally Onyango

7/10/19

Date

This research has been submitted for examination with my approval as a University Supervisor.

Mr. Luther Otieno.

Date

27-10-200

DEDICATION:

Dedicated to the memory of my daughter, Jaqueline, whose loss made me find consolation in books.

ACKNOWLEDGEMENT

In the process of carrying out this research project I benefited from assistance and encouragement from many individuals and institutions. It would not be practical to name each one of them. Still, I wish to acknowledge their invaluable contribution to this research. It is however, necessary for me to mention a few of them.

I would like to thank my supervisor, Mr Luther Otieno, for his guidance throughout the research period. My special gratitude goes to my boss, Mr. David Percival, Managing Director, Kenya Vehicle Manufacturers Ltd and Accounts Department staff, in particular Nathan Juma, without whose support it would not have been possible for me to complete this project.

My friends, Jane Gichuki and Penina Omondi had to sit long hours to type this work. I extend my sincere thanks to them for this.

I would also like to thank my colleagues in the MBA Executive programme, in particular Elizabeth Mugo, for the encouragement to continue with the project when at times my spirits were low.

Finally, I wish to acknowledge the contributions of my family towards the completion of this project. My special thanks go to my husband, Edward, my children: Evans, Allan, Patrick and Natasha, and my sister Priscilla for their

encouragement, love, patience, understanding, and emotional support they gave me in the course of my study. I am so grateful to my niece, Dina Ayiera, who gave me invaluable support.

ABSTRACT

The objectives of this research were firstly, to find out factors managers consider when making decisions to declare stock dividends and secondly, to establish if shareholders gain from such declarations, in terms of increased dividends. In order to achieve these objectives both primary and secondary data were used. The information for the first objective was obtained by the use of a questionnaire, which was completed by 22 companies. For the second objective, the sample comprised 62 bonus issues made during the period 1994 to 1998, derived from annual reports of the companies in this study.

The study identified six important factors that managers of companies listed at Nairobi Stock Exchange consider before issuing bonus shares. These are: cash conservation, giving recognition that some retained earnings have been permanently committed in the firm, creating greater interest in the firm's share, broadening of shareholders base, correcting of a situation where retained earnings have grown disproportionately large in relation to capital contributed by shareholders and signaling better future prospects.

On the second objective, the study established that shareholders gain from stock dividends in terms of increased cash dividends. The average increase of 10.23% experienced during the period covered by the study was found to be statistically significant.

1.0 CHAPTER ONE: INTRODUCTION

1.1 Background

One of the major decisions that the management of a company has to make is its dividend policy. Dividend refers to the portion of earnings that is paid out to the shareholders. The amount paid out as dividend reduces the retained earnings in the company and this, it is argued, might have negative effect on the amount of internal financing. The basic dividend model (Gordon 1962), says that, if company pays out more cash dividend, the price of its shares will increase. However with more cash dividend being paid out, the less the retained earnings for reinvestment. This may hamper the future growth of the company, especially if the company cannot raise additional capital. Share prices in turn will end up being depressed. It seems apparent that dividend decisions have, therefore, two opposing sides to it. The management of the company has the responsibility of coming up with dividend policy that would strike the balance between current dividends and future growth, thus maximising the value of the firm. Companies have adopted different forms of paying dividends; the most common of which are cash dividends and bonus issue.

Cash dividend is the most common form of distributing earnings to owners of the company. It is normal that cash dividend is paid out of the current year's net profit. The balance of the year's profit is taken to reserves. A company can pay dividends from past years' retained profits as long as it is not from capital reserves. For a cash dividend to be paid the company should have

adequate cash in its bank account, otherwise arrangements must be made to borrow the needed funds.

Bonus issue is another popular form of dividend payment. It occurs when the board of directors authorises a distribution of common shares to existing shareholders of the company. Bonus issue has the effect of increasing the number of outstanding shares of the company. The distribution is done proportionately and, therefore, shareholders end up with the same proportionate ownership they had before the Bonus issue. There is no possible loss of control as far as shareholders are concerned.

Investors pay great attention to dividends, firstly because dividends represent the return to the shareholders that put money at risk in the company in the form of equity. Secondly, corporations pay dividends to reward existing shareholders and to encourage others to subscribe to new issues of common stock at fair prices. The third reason that makes investors pay attention to dividend could be because it is only through dividends or the prospects of dividends that they receive a return on their investment or the chance to sell their shares at a higher price in the future (Hess 1987)

Though substantial empirical research has been done in the area of dividends, there is a long-standing controversy on the effect of cash dividend on the value of a company. Researchers tend to disagree that a firm's dividend policy can affect the prices of its shares. There exists a clear

distinction between those who believe that dividend policy is irrelevant in the determination of the firm's value and those who believe it is relevant.

Spearheading the irrelevance theory are Franco Modigliani and Merton Miller (1961) who argue that the value of any firm depends on its earnings, which result from its investment policy. They add that the division of earnings between dividend and what is retained is not important in determining the value of the firm. The higher the dividend, the less the investor receives in capital appreciation, no matter how the firm's business decisions turn out. Further more Modiglian and Miller argue that there is always cash for investments.

Researchers, advancing strong arguments to support the relevance of dividend in the determination of the value of the firm includes Myron Gordon (1963) and John Litner (1962) with their "Bird-in-the-hand theory. They assert that investors are surer of receiving dividend payments than the income from capital gain, that results from retaining earnings. Their thesis is that, investor value expected dividend more highly than the expected capital gains.

Litzenburger and Ramaswamy (1979) support a third theory, which is based on the tax effects of dividend. This theory asserts that because capital gains are taxed at lower rates investors are better off when dividend payoff rate is set at lower than at higher levels.

Irrelevance theory implies that shareholders are indifferent between receiving returns as dividend or as capital gains. If a lower dividend is paid, the capital gains will increase while a higher dividend will lower the capital gains. Overly the returns will be equal in either case. This theory was based on assumptions that have proved unrealistic, among them, the assumption that there are no taxes. When later M and M relaxed this particular assumption, they argued that shareholders are better off with capital gains as these are taxed at a lower rate than cash dividends. In some cases capital gains are not taxed at all.

While the debate on cash dividend is still raging, with no sign of resolution in the new future, there seems to be a general consensus among scholars on the effect of bonus issues on the value of a firm. All the studies carried out in this area have more or less come to the same conclusion that in the long run bonus issues do not have any effect on the value of the firm. The first study was carried out by C.A Baker in 1958. This study has been replicated several times in the recent years and they have all come to the conclusion that bonus issues do not have a long-term effect on share prices. Another study, which used an entirely different methodology, carried out by Eugene Fama, Lawrence Fisher, Michael C. Jensen, and Richard Roll (1969) also arrived at similar conclusion.

Theoretically, therefore, a bonus issue does not add any value to an investor.

It is seen as nothing more than a recapitalisation of the firm which involves passing accounting entries to transfer figures from reserves to share capital

account. The proportionate ownership of the shareholder remains the same before and after the bonus issue. The market price of the stock should decline proportionately, so that the total value of their holdings stays the same. The only time the share prices can go up is when bonus issue is accompanied by an increase in earnings and cash dividends. If this is not the case, the dilution of earnings causes the price of the share to drop by the same percentage as the bonus issue. Weston and Brigham (1993), assert that the fundamental determinants of stock price are the underlying earnings and cash dividends per share, and that bonus issue merely cuts the pie into thinner slices.

Theory not withstanding, there are several aspects of bonus issue that make the boards of directors adopt it as a form of payment to the investors. Several factors have been identified as responsible for the management decision to issue them. Pandey (1999), observes that the following factors might impact on stock dividend decision:

- 1) Conservation of cash since through bonus issue, a company is able to pay dividend without using cash. Unused cash can then be invested in projects with Positive Net Present Value. Instead of going for external financing a company can retain its funds that would otherwise be distributed to shareholders.
- Raising of dividends, assuming that increased cash dividends accompany bonus issues.

- 3) Bonus issue may be used to signal higher future profits. They should only be declared when a firm has better future prospects, otherwise it would experience dilution of earnings. This can have a very negative effect on the value of the firm, which will translate to losses to the shareholder.
- Placing share prices in a more popular trading range. A bonus issue reduces the unit price per share therefore making them affordable to investors who previously perceived the price as too high.

Van Horn (1997), Bhalla (1987), and Solomon (1966), give further reasons as to why firms issue bonus shares. These include; Having positive psychological value as it is associated with the prosperity of the company; Retaining proportional ownership of shareholders i.e. shareholding will increase without bringing in new shareholders; and Loan agreement restrictions that prohibit or limit the declaration of cash dividends.

In Kenya bonus is a very popular form of making dividend payments to shareholders. In the last five years about 20% of companies quoted on the Nairobi stock Exchange have declared bonus issue in each year. At the same time bonus issue has become very controversial in Kenya. It is possible that some companies might have knowingly or unknowingly abused it. The cases that can be cited include Kenya Finance Bank, which in 1994 and 1995 declared bonus issue and was put under receivership a few months after the

1995 dividend declaration, and Unga Group, which in 1998 issued stock dividend at the rate of 5 shares for each share held and yet the company incurred huge losses in that year.

One would expect bonus shares to be issued by only profitable companies. Directors or their agents (managers) are better placed to assess the profitability of their company. Studies carried out in Kenya have been on cash dividends, among them a research by Iminza (1997) on the effect of dividends on share prices of companies quoted on the Nairobi Stock Exchange. However no substantial work has been done on stock dividends. The aim of this study is to fill this gap

1.2 Statement Of The Problem

Bonus issue is a very popular way of rewarding shareholders in kenya. No substantial research has been carried out to establish the benefits that accrue to companies and their shareholders as a result of such issues. The research therefore seeks to examine reasons (factors) behind declaration of bonus issues. The research further seeks to establish if there are benefits that accrue to shareholders as a result of bonus issues.

1.3 The Objective Of The Study

The objectives of this study are twofold:

 To identify factors that managers consider in the process of declaring bonus issues. ii) To establish whether or not shareholders benefit from such bonus issues. An increase in the immediate subsequent cash dividend after the bonus issue is taken as a surrogate for benefit to the shareholders.

1.4 Importance Of The Study

The research will be beneficial to several stakeholders. A major assumption in this study is that the aim of management is to come up with a dividend policy that would maximise the value of the firm. An effective dividend policy ensures success in raising funds for worthwhile projects. The findings of this research can be used by management in formulating policy on bonus issues. Investors would use the knowledge to make informed investment decisions. The knowledge gained from the research would enable the financial advisors to advise their client appropriately. This study may trigger the interest of researchers to carry out further research on other areas of bonus issues, for example using share prices to determine their effect on the value of the firm in Kenya. There may be a study relating bonus shares to the underlying characteristics of firms as contained in their annual reports.

Having given the background information on bonus issues and identified the need for research in this area, it is important to look at what the other authors have written on this subject. Chapter two covers the literature review on the subject.

2.0 CHAPTER TWO: LITERATURE REVIEW

This chapter is divided into three sections. The first section is introduction, the second covers the effect of bonus issue on share prices, the third section looks at the reasons why it is desirable and finally the third section is conclusion.

2.1 Introduction

Bonus issue is a corporate practice, dating back to 1682 when East India Company, declared one hundred percent bonus issue. From that time payment of bonus shares has been a common way of "rewarding" shareholders Researchers have for a long time wondered why companies declare bonus issue. From an accountant's perspective this is an accounting entry transferring amounts from retained earnings to share capital account. It increases the number of equity shares outstanding without changing the shareholders proportional ownership of the company. Acknowledged academics assert that there are no benefits accruing to shareholders from issuing of bonus shares. Such distributions just cut the same loaf of bread into thinner slices (Baker 1958). Bonus shares, therefore, do not have any effect on the firm and by extension the wealth of its investors. If that holds, the question is, Why do companies adopt it as a form of reward to shareholders?" The related question is why do managers and investors alike behave as if bonus shares increase wealth and add value? Answers to these questions require empirical studies, specifically studies to ascertain the effect of bonus issues on the value of a firm and to find reasons why they become necessary.

Researchers in other countries, especially in the U S, have attempted to address this issue. In Kenya, however, no substantial research has been done on the subject of bonus shares and this helps explain lack of Kenyan literature on this subject in our local libraries. This forces a researcher in this area to rely on literature of foreign-based studies, particularly in the United States of America.

2.2 Effect of Bonus Issue on Share Price

Substantial researches that attempt to ascertain the effect of bonus issues on share prices have been done. One of the earliest was a research carried out by C. Austin Barker in 1958. Mr. Baker sought an answer to the questions: "Do bonus issues have long-run effects on market price of shares?" Mr. Barker (1958) studied all the dividend issues of five percent or more paid in common shares on New York Stock Exchange during the years 1951 through 1954. To enable him model the relationship between declaration of bonus shares and movement in share prices he classified stock bonus issues as follows: those which are accompanied by cash dividend increases; those with no increases or with actual decline in cash dividends; and those omitting cash dividends altogether.

The reason for this classification was to enable him measure separately the effect of bonus issues which are accompanied by increases in cash dividend and those that are accompanied by reductions or no change in cash dividend.

Having taken six months prior to the ex-dividend date as the base, he compared this with prices at ex-dividend date and six months after the ex-dividend date. The movements of all the share prices in relation to the base rate were determined at the ex-dividend rate and again six months later. A comparison was made between these and actual market prices to determine the real gain or loss as compared to the general state of the market. The findings of the investigation were:

- The 190 companies which accompanied bonus issues with cash dividends increases had a real price gain averaging 9% over the six months preceding the ex-dividend date and 8% gain six months after the ex-dividend date.
- 2) Where there was no cash dividend increases accompanying bonus issue, the prices of the stocks held even with the general market through the ex-dividend date and then dropped 12% below the general market in the following six months.
- 3) For companies that paid bonus shares both with and without cash dividend increases, it came out that they achieved a real

price gain in the years their bonus issues were accompanied by cash dividend increases and that without exception same companies share prices declined relative to the market when they were not accompanied by cash dividend increases.

The conclusion drawn from Barker's investigation was that bonus issues per share have no measurable market value i.e issuing of bonus shares does not have long term effect on the value of a firm.

Researchers have replicated Baker's study on the effect of bonus issue on stock prices and all of them have come out with the same results. Eugene Fama, Lawrence Fisher, Jansen and Richard Roll (1969) a carried out a similar study using an entirely different methodology. They too reached similar conclusions as those of previous studies, that issuing of bonus shares does not in the long run affect the value of a firm. That research using different methods reach identical conclusions add to the consistency of the conclusion.

In the short run, however, studies have shown that bonus issue announcements affect share prices. Mark S Grinblatt, Ronald W Masulis and Sheridan Titman (1984) investigated the effect of bonus shares and share split announcements on share prices. Their conclusion was that share prices react positively to bonus issue announcements. The inconsistency of this conclusion with those of the studies above can be explained by the information content of bonus

issues. In the short run share prices will respond positively to bonus issue announcements. However if the investors' expectations are not realised, prices will fall back to their correct levels.

Grinblatt, Masulis and Titman analysed the returns on three days around the announcement date. These returns were compared with the average daily return of subsequent benchmark period of forty trading days. To get the returns they used the Daily Returns File of the American or New York Stock Exchange. The investigation revealed that for the total sample of 1792 firms the mean two-day returns around the announcement date was 3.41 percent. For the benchmark period of forty trading days subsequent to the announcement the mean was 0.10 percent. The three researchers took into consideration the concern that the increase in returns around the announcement period could have been caused by other announcements, other than bonus issue. The prices could have reacted to news of, say, mergers, cash dividends or reported earnings. To rule out the effect of this a sample of 84 pure bonus issue announcements and 244 pure share split announcements, where no contaminating announcements occurred, were analysed. The mean two-day return around the announcement was 5.87 per cent for bonus issues and 3.29% for share splits, while that for forty days subsequent to the announcement was 0.14 for bonus issues and 0.16 for the splits. Using the t- statistic, day 0 and day 1 returns were found to be significantly higher than for the benchmark period. The positive returns could not be attributed to simultaneous or

subsequent dividend increases as analysis of the sample with no cash dividend announcement indicate that the announcement effect is not as a direct result of cash dividend increases as has been suggested by other researchers. The results of this study influenced Grinblatt, Masulis and Titman (1984) to hypothesise those firms signal information about their future earnings equity values through bonus issues and share split.

Due to constrain placed on this researcher, this study is not going to look at the impact of bonus issues on share prices. These constraints include availability of time, availability of reliable share prices, and the difficulties that would be experienced in trying to separate the effects of other factors unrelated to bonus issues announcement, as a model for doing this has not been developed for the Kenyan Market. However, the literature that has been written and the researches carried out elsewhere on the effect of bonus issues on share price have been included here to help the reader appreciate the other reasons that make managers declare bonus issues.

2.3 Reasons for Issuing Bonus Shares

Several reasons are cited in finance literature as to why firms issue bonus shares. Pandey (1999) summarises the following as the positive aspects of stock dividend: Conservation of cash, raising of dividends, indication of higher future profits, and placing stock prices in

a more popular trading range. Scholars, Van Horne (1997), Bhalla (1987), and Solomon (1966) give additional reasons: tax benefits, growth of ownership, positive psychological value, and loan agreement restrictions that prohibit or limit the declaration of cash dividends.

Signalling effect of bonus issues

In an inefficient market managers have information about current and future earnings unavailable to investors. Investors operating in such a market may sell their investments at prices outside their true values. It is suggested that, managers can use dividend payment to convey information about the future earnings to investors. This debate is inconclusive. Miller and Modigliani (1961) in a follow-up to their 1958 study suggest that the relationship between dividend announcement and security price movements might be attributed to the information content of cash dividends. This notion is supported by empirical studies of Ahorony and Swary (1980), Kwan (1981), and Woolridge (1982). It is possible that, bonus dividends are seen by investors to indicate management's belief about the favourable prospects of the company. Bonus dividends appear to be a relatively inexpensive and a clear way of signalling. There are no signalling costs in the form of financing expenses and higher tax expenses involved with bonus issue.

Similar studies have been carried out on bonus dividend signalling effect. Foster and Vickrey (1978) research is one of the few which concluded that bonus issue announcements are interpreted by investors as signals from managers. They sought to find out if investors change their expectations about the future earnings and re-value the firm's shares as a result of bonus issue. Their samples comprised 82 bonus dividend announcements made during 1972 to 1974. They analysed daily market model residuals around the declaration date working on the hypothesis that mean of the declaration day residual was greater than zero Forster and Vickreys results showed that the mean day residual of 0.02 was significantly greater than zero at 0.025 level of confidence i.e. have information content. This study concluded that bonus dividends have information content. Their sample, however, included firms, which paid cash dividends. They did not attempt to separate the effect of bonus issue from cash dividend announcements and other intervening factors. Woolridge (1983) made several refinements in the Foster and Vickery (1978) study. Their sample excluded firms which had concurrently paid cash dividend or which paid within the past three years. They also excluded firms that had made what they consider significant announcements. Woolridge (1983) then employed the Comparison Period Return Approach to determine if the mean daily returns of the 60 days before and after the bonus issue announcements were statistically different.

The empirical results indicated that there was a significant difference between the mean observation period (0.558 per cent) and the mean comparison period (0.068 percent) at the .01 level. These findings support the notion that bonus issues are interpreted by investors as management signalling device.

Lakonishok and Lev (1987) used a different approach from the two studies above to test the signalling effect of bonus shares. The test sample for their study consisted of 1015 share split and 1257 bonus dividend events covering the period 1963 to 1982. They further constructed a control sample by matching every company in the test sample with a company, which had more or less same asset size. They analysed the performance of companies, which had issued bonus shares in terms of growth in earnings and in dividends. examination was carried out for five years prior to and five years after the month in which bonus issue was announced. After measuring growth in earnings and dividends for the entire sample, a summary was made using simple average and median. The findings of this investigation did not provide support for the signalling motive of bonus There was a very modest above-average earnings performance of bonus issuing firms in the pre-announcement period. There were hardly any differences in dividend growth between the test and the control sample.

Cash Conservation:

An important reason given for distribution of bonus shares is to conserve cash resources, which can be invested in worthwhile projects. Cash is conserved whenever a company reduces cash dividend or eliminates it altogether. Barker (1958) investigated the effect of bonus issues on cash conservation. Out of the 224 bonus issues he studied only 34 met cash conservation criterion. This translates to 15% of the total number studied, which is not large enough to draw a conclusion that conservation of cash is a major objective of bonus issue. Another investigation by Eiseman and Moses (1978) also concluded that in majority of firms sampled bonus issue did not translate into cash conservation.

Tax Benefit:

On the question of whether or not bonus issues offer tax benefits to investors, Barker's investigation concludes that this is a fallacy. The investor would pay capital gains tax on selling bonus shares just as he would on his original holdings. Similarly he would pay personal tax on cash dividend received from his bonus shares just as he would on cash dividend from his original holdings. Baker's position on tax benefit is also shared by Eiseman and Moses (1978).

Growth of Ownership:

Widespread stock ownership is viewed favourably because it improves the marketability or shares. To find out if bonus issues result in increase in shareholding, Barker took the 224 bonus issues and compared their shareholder growth with those companies, which had not issued bonus shares. The growth rate was 20% during 1951-53, which was 15 percentage points above the gain shown by companies which had not issued bonus shares. This indicates that shareholders base is broadened when there are an issue of bonus shares.

Maintaining Popular Price Range

Bonus issues, like share splits, reduce the share prices. This, it is claimed, keeps the prices of shares within some optimal rage. The assumption is that shares with a low unit price appeal to a wider investing community unlike shares with relatively high unit price. When shares are highly priced some investors will not be able to buy. On the other hand wealthy investors might find it cheaper when securities are priced high as they save in brokerage costs. These costs are based on the number of shares sold. There is an optimal price range that equilibrates the preferences of these classes of investors. There are industry norms for share prices and management use share splits and bonus share distribution to adjust share prices to these norms. Lakonishok and Lev (1978) carried an investigation to ascertain the effect of bonus issue on volume of trade. They analyzed the monthly number

of shares traded relative to shares outstanding at the same date for a given stock. Their study covered five years. The findings of the investigation indicate that there was a statistically significant increase in trading volume in the announcement month.

Closely related to this research is an investigation carried out by Eiseman and Moses (1978) to explore reasons why corporate managers issue bonus shares. They sent out a questionnaire to a group of NYSE companies, which had issued bonus shares, and also to a group which had not. The questionnaire was divided into two parts. The first part, which was made up of 17 closed-end questions, was designed to get management's attitude towards bonus issues. Both groups were given the same questions. Part two; was designed to ascertain the respondents' knowledge of the published literature on bonus shares and their attitude towards them. Here the two groups were asked different questions. The dividend payers alone were asked why their companies issued bonus shares while non-dividend payers alone were asked why their companies did not issue bonus shares. Their findings are summarised below.

A large majority of respondents from both groups felt that bonus shares ultimately increase the number of shareholders in the firm. On the claims that increase in the number of shareholders is beneficial to the firm, as it would make stock more attractive, the paying firms agreed while the nonpaying firms rejected the claim.

- Respondents from the two groups agreed that issuing bonus shares conserve cash. However, Eisemann and Moses (1978) felt that this notion results from confusion of bonus issue with cash dividend policies. Bonus issues conserve cash only if they replace cash dividends. Of the 80 stock dividend paying firms in their sample only four actually reduced cash dividends during 1974, thus few of the bonus issues actually resulted in conservation of cash.
- On the question of whether or not bonus shares increase investors' aftertax returns through either an increase in after-tax shareholders receipt or
 an increase in the total value of his stockholdings, approximately 82% of
 the dividend paying officers agreed while the non-paying officers were
 divided. The argument of those agreeing was that shareholders could sell
 the bonus shares and pay taxes on the capital gain at the capital gain tax
 rate, which is lower than ordinary income rate. Eisemann and Moses
 (1978) believe that this argument does not hold as investor who is selling
 stock dividend is doing nothing more or less than selling a part of his
 original ownership, an option available to him with or without a bonus
 dividend.
- Regarding the value of the stockholding both groups felt that stock prices would not fully adjust to occasional bonus issues. Although there is no direct statistical evidence on small bonus issues, the evidence on share splits and large bonus issues suggests that full price adjustment does occur.

- The dividend-paying group strongly agrees that issue of bonus shares may have information content while majority of non-paying group disagreed. Eismann and Moses (1978) interpretation is that "any improvement in share price observed by corporate managers could, of course, be the result of coincident changes in cash dividend policy or improved earnings."
- The non-payers felt that cost was a major determinant of whether firms issue bonus shares while officers from the paying firms felt it was not.
- The payers, in response to the open-ended question asking them to list, in order of importance, the reasons why their companies issued bonus shares in 1974, gave the following results:
 Historical company practice was given as the number one reason. This was following by "cash conservation" and "increasing yield to shareholders", which tied in number two position. The other reasons, which were given for issuing bonus shares included: Expanding equity representation; Expression of confidence in the firm; popular with shareholders; and, Means of increasing cash dividends.

Non payers gave the following as the reasons why they had not issued bonus shares: High administrative costs was viewed as one of the most important reason together with the fact that the net position of the shareholders does not change as a result of bonus issue.

The other reasons which got high rating were: the effect of dilution on earnings, that would result from bonus issues, the fact that shareholders prefer cash dividend; and price reduction that would follow such bonus issues. The other reasons that were listed are: bad earnings performance by the company, not appreciated by stockholders, institutional investors do not like them, desire to restrict number of shareholders, no need to conserve cash, continually paid cash dividends, and preference for share splits. From these responses the reasons that make companies not pay bonus shares are many.

In conclusion, Eimann and Moses (1978) believe that some managers continue to support bonus issues despite the limited benefits of such distributions to the shareholders. However, such managers believe shareholders gain from bonus issues. Furthermore the maximisation of shareholders wealth may not be the only goal guiding these managers. Many managers consider the goals of the other group, for example those of management. And finally some managers may know the limited value of bonus issue, but still fear stockholders reaction to a change in the company's historical practice of bonus issue. Agency theory tells us that there may be conflict between the interest of managers and shareholders.

Studies done in Kenya on this area have examined the area of cash dividend, among these by Karanja (1987) and Iminza (1997). Karanja, emphasising on cash dividends, looked at the major determinants of dividend policy in Kenya. Iminza investigated the information content of cash dividends in companies

quoted in the Nairobi Stock Exchange. There is, therefore, a need for research in the area of bonus issues.

Conclusion.

In the short run share prices react positively to bonus issue announcements as they are perceived by the investors to convey information from management that the future is bright.

If the expectations of the investors are not realised, prices fall back to their right levels. In the long run, however bonus issues do not have any effect on the value of a firm. Despite its limited value, managers use bonus issues for various reasons. Among these are: to broaden shareholders base; to conserve cash (this has not been proved by empirical studies); to recognise permanently committed retained earnings and to create greater interest in the share.

The studies in bonus issues have been done in other countries. No substantial study has been carried out in Kenya on this subject. This research has been designed to address this problem.

3.0 CHAPTER THREE: RESEARCH DESIGN

3.1 The Population: -

This consisted of all companies that were quoted on the Nairobi Stock Exchange in the five years from 1994 to 1998. The study was restricted to quoted companies because of the difficulties that would be experienced in getting data from private companies.

3.2 The Sample and sampling design:

The sample frame comprised of companies that declared bonus issues in the five years from 1994 to 1998. These were 39 in number with a total of 62 bonus issues in that period, some companies having made more than one issue (see appendix 1). One of the companies, Kenya Finance Company has been placed under receivership. Since the number of companies in the sample frame was not large all were included in the sample drawn to examine factors that influence managers decision to make bonus issues. Likewise all the 62 issues were included in the sample drawn to establish whether or not shareholders benefit from such issues.

3.3 Data Description and Collection Methods:

3.3.1 Primary Data

To address the first research objective, namely finding out the relative importance of factors that influence bonus issue in Kenya, primary data was used. The data was collected through a questionnaire (see appendix 2) which was dropped and picked by the researcher. Through questionnaire the

researcher sought the opinion of Chief Financial Officers of companies listed at the Nairobi Stock Exchange on fourteen specific factors listed in the finance literature as important in making a decision as to whether to pay dividends or not. The questions were both structured and unstructured. The Chief Finance Officers were approached because of their close involvement in stock divided decisions.

A total of 39 companies paid bonus issues during the period covered by this study. One company, Kenya Finance Bank, has since been put under receivership, bringing the number of companies studied to 38. Because of this it was not possible sending a questionnaire to the company.

Out of the 38 questionnaires that were sent out 22 were returned and were used in this study. The response rate was fifty-eight percent. This is above average response rate. In the questionnaire 14 common factors were listed. The Chief Financial Officers of the companies were asked to rate these factors on a four point Likert scale. The variables of rating were: Very important, Important, Slightly important and Not important. They were given rating of 4,3,2 and 1 respectively. The factors were:

- 1) To conserve cash
- To give recognition that some retained earnings have been permanently committed to the firm.
- 3) To broaden shareholders base
- 4) To keep the market price of the firm's shares within a desired range

- 5) To have positive psychological value
- 6) To indicate higher future profits
- 7) To gain tax advantage for shareholders
- 8) To correct a situation where retained earnings have grown disproportionately large in relation to the capital contributed by the shareholders.
- To pay dividend in cases where loan agreements prohibit or limits the declaration of cash dividend.
- 10) To prepare for a major fund raising exercise
- 11) To create greater market interest in the share
- 12) To signal better future prospects
- 13) As compensation for paying lower cash dividends than shareholders expect.
- 14) Due to inability to pay cash dividend where shareholders are used to one.

3.3.2 Secondary Data

For the second objective, to establish benefits that accrued to shareholders from receiving bonus issue, secondary data was used. The researcher obtained data from published accounts of the sampled companies from the secretariat of the Nairobi Stock Exchange.

During the period covered by the study a total of 62 bonus issues were made.

The following data, needed to establish if there was improvement in dividend per share, was extracted from these accounts for the entire sample.

1) Rate of the bonus issue.

For example Firestone E.A Ltd. issued 1 share for every two held. This ratio of 1:2 translates to a rate of 50%.

2) Rate and amount of cash dividends prior to the bonus issues.

The rate of dividend is the immediate cash dividend before the bonus announcement expressed as a percentage of the nominal value of the share. This is adjusted for the bonus issue to facilitate meaningful comparison with the after capitalisation immediate rate.

- 3) Rate and amount of cash dividend for period after the bonus issue.
 - The rate of dividend is obtained by expressing the immediate dividend after capitalisation as a percentage of the nominal value.
- 4) Equity capital before and after the bonus issue.

For example the equity capital of a firm with 1,000,000 shares of Kshs 5 each before the bonus issue will be Kshs 5,000,000. If the firm declares a bonus issue of 1 share for every 2 held the equity capital after the bonus issue will stand at Kshs 7,500,000.

Having obtained the data needed for this study the next step was to analyse and obtain findings.

4.0 DATA ANALYSIS AND FINDINGS

4.1 Factors considered important in Making Bonus Issue Decisions

As mentioned earlier Chief Financial Officers were asked to rate the fourteen factors listed in the questionnaire by giving scores of 1 to 4 to each factor in order of importance. The ones, which were considered very important, got the highest score of 4 and the score of 1 was given to factors considered not important in bonus issue decisions.

Scores earned by every factor from the 22 companies, which responded, were tabulated. Total score for each factor was calculated (see appendix 3). The next step was to find a representative score for each factor. This requires that from the respondents scores averages be calculated and the level of concurrence amongst respondents on a particular factors estimated using standard deviation (see appendices 4–7). For example, standard deviation of zero on a particular factor would imply total agreement.

The average score rating was as follows:

| From | То | |
|------|------|--------------------|
| | | |
| 1 | 1.49 | Not important |
| 1.5 | 2.49 | Slightly important |
| 2.5 | 3.49 | Important |
| 3.5 | 4.00 | Very important |

Table 1 shows a summary of how managers responded.

| FACTOR | Very Impo | rtant | Importa | nt | Slightly Importa | | Not Impor | tant | TOTAL | |
|---|-------------------|-------|-------------------|----|-------------------|----|-------------------|------|-------------------|-----|

| | II | | | | Į. | | | | | |

In terms of ranking, cash conservation came out as the number one factor. This was followed by, "consideration of giving recognition that some retained earnings have been permanently committed", as the number two factors. Creating market share took the third position. Three factors tied on position four and these were: broadening of shareholders base; correcting a situation where retained earnings have grown disproportionately large in relation to the capital contributed by the shareholders; and signalling better future profits.

Cash Conservation

An overwhelming majority of respondents considered cash conservation as either very important or important factor in their decision to issue bonus issues. Only one respondent felt that cash conservation was slightly important and two that it was not important in the decision to declare bonus issues. This factor's average scored was 3.23, with a standard deviation of 0.81, indicating that most managers agree that it is an important factor in determining whether or not a company pays bonus issue.

Although most managers felt that cash conservation was an important factor, an investigation into the 62 issues covered under this study did not lend support to this. As has been mentioned earlier cash conservation occurs only when bonus issue is used to supplement a partial reduction in cash dividends or when it replaces cash dividend altogether. Out of the 62 issues studied only

10 reduced or eliminated cash dividends altogether. This translates to 16%, which is not large enough.

These findings are consistent with the results of Baker's (1958) study discussed in the literature review.

Recognising Permanently Committed Retained Earnings

Having achieved an average score of 2.77 and a standard deviation of 0.87 this factor was rated as important, but below cash conservation. Retained earnings invested in permanent assets is capitalised, thus it may not be possible to use the same in paying dividends. Four respondents considered this factor as very important while eleven gave it a rating of "Important". Six and two considered it slightly important and not important respectively.

Creation of greater Market interest in the share

This factor ranked third in rating. Payment of bonus issue is usually received positively by the market. Investment in the share is encouraged and this helps in raising or keeping its price high.

With an average score of 2.68 and a standard deviation of 0.78, this factor was considered important by majority of the respondents. Three respondents considered it very important while ten gave it a rating of important. Eight thought it was slightly important in their company's decision to issue bonus

issue. Only one manager responded that it was not important. This factor took position three.

The managers response to this factor is consistent with Lakonishok and Lev (1958) study discussed in the literature review section.

To signal better future prospects in earnings

This factor achieved position four overall. The average score for the factor was 2.64, with a standard deviation of 1.05, meaning that it is considered important, though the views of the respondents are diverse.

Bonus issues are usually declared only in cases where there is expectation of rise in earnings to cater for the additional shares. If this were not the case the company would suffer dilution of earnings, which is not desirable for the performance of their share in the market.

Five respondents felt that this factor was very important and eight that it was important. Only five and four responded that it was slightly important and not important in their decision to declare bonus issue respectively.

Broadening of Shareholders Base

This factor achieved an average score of 2.64 and a standard deviation of 0.95, indicating that majority of the respondents considered it important. A total of fourteen managers considered it as either important or very important

with only two indicating that it was not an important factor in their decision to issue bonus issues.

Bonus issues usually increase the number of shareholders in a company, as those shareholders that are in need of cash sell their shares in the market. With more people participating, the availability of the company's shares in the market will increase and this is considered desirable. Broadening of shareholders base as a reason for paying stock dividend is consistent with the findings of Baker's (1958) study covered in the literature review.

An investigation into the change in the number of shareholders after the bonus issues showed that there was an increase of 6%. For the companies which responded on this question, the total shareholders increased by ----from 304236 before to 323366 after the bonus issue.

Listed as slightly important, were the following factors shown in Table 2.

Table 4.2: Factors listed as slightly important.

| Factor | Score | Standard |
|--|-------|-----------|
| | | Deviation |
| To keep market price with desired range | 2.27 | 1.03 |
| To indicate higher profits | 2.05 | 0.84 |
| To compensate for lower cash dividends | 2.05 | 1.00 |
| To gain tax advantage for shareholders | 1.91 | 0.92 |
| Inability to pay cash dividend | 1.77 | 0.97 |
| To prepare for major fund raising exercise | 1.64 | 1.05 |

The factor that was considered not important by respondents was "to pay in cases where loan agreements prohibit or limit declaration of cash dividend". Seventeen respondents stated that it did not affect their decision to issue bonus shares. This implies that in Kenya the majority of loan covenants do not put restrictions on payment of dividends. On the questionnaire, space was provided for any other factor that was not listed. Two companies, Jubilee Insurance Ltd. and Housing Finance Company of Kenya, responded on this space. Both indicated compliance with legal requirement as a very important factor in their decision to issue bonus issues.

4.2 To Establish whether or not Shareholders Benefit from Bonus Issues

4.2.1 The market as a whole

To achieve the second objective of the study annual cash dividend paid to shareholders immediately before was compared to annual cash dividends declared immediately after capitalisation for all the bonus issue payments made during the period 1994 - 1998. In order to make a meaningful comparison the cash dividend and rate paid before capitalisation was adjusted to the equivalent dilution value taking into account the increase in number of shares outstanding after the stock dividend. For example George Williamson Group paid a cash dividend of Kshs.5 per share (100% of the nominal value) before declaring a bonus issue, the adjusted cash dividend came to Kshs.2.50 per share (50%).

UNIVERSITY OF NAIROBI LIBRARY

The difference between adjusted dividend and the actual dividend paid after capitalisation was calculated for the entire sample. The mean, median and standard deviation were worked out for adjusted dividend and for the actual dividend paid after capitalisation. The test was to see whether the means of dividend before and after the capitalisation differ. The two means were compared and the difference determined. The difference between the two means should be zero for hypothesis that bonus share do not add value to be accepted.

To test for the statistical significance of the difference, i.e. in the two means the following hypothesis was set:

$$H_0: \mu = 0$$

$$H_A$$
: $\mu \neq 0$

Where μ = the difference between the two means.

This tests whether the difference between two means is zero. If the difference is zero then there is no difference. For the purpose of our study a difference of zero is interpreted as no increase in subsequent divided after a bonus issue.

Setting the level of significance at 0.05 the null hypothesis is rejected when the difference is \leq - 1.96 or Z \geq 1.96

The average adjusted dividend per share before capitalisation was Kshs 2.185 (36.94%) with a standard deviation of 23.5%. After capitalisation this figure moved to Kshs.2.91 (47.17%) and a standard deviation of 34.6%. The

difference between the two means was 10.23%, cash dividends having gone up.

Testing for the significance of the difference experienced in the market as a whole and using the above formula, the following findings was obtained:

$$Z = \frac{x - \mu_0}{\delta / \sqrt{n}}$$

$$Z = \underbrace{0.1023 - 0}_{0.2715 / \sqrt{62}}$$

Using 0.05 level of significance the null hypothesis is rejected as Z is greater than 1.96. The difference is statistically significant. This means that after capitalisation the cash dividend paid to shareholders on average increase for the market as a whole.

Of the 62 bonus issues in the study 48 were followed by increases and 10 by decreases in cash dividend to shareholders. In 4 issues the companies paid the same amount of dividend as before. (See appendix 8).

The highest rate of increase was recorded by Kenya Power and Company Ltd. (120%) followed by E A Packaging (70%). Unga group, with a rate of 66.7% took the third position. All the three companies are in Industrial and Allied Sector.

The highest reductions were experienced by Lonrho Motors (53%), BAT Kenya Ltd. (32.5%), George Williamson and Kapchorua at 30%.

The average rate of bonus issue came to an average of one new share for every 1.22 shares held or 81.9%.

Table 3 shows the distributed rate of bonus dividends.

Table 4.3: Distributed Rate of Bonus Dividends.

| FROM | ТО | NO OF COMPANIES |
|-------|-----|-----------------|
| % | % | |
| 0 | 20 | 12 |
| 21 | 40 | 15 |
| 41 | 60 | 15 |
| 61 | 80 | 1 |
| 81 | 100 | 12 |
| OVER | 100 | 7 |
| TOTAL | | 62 |

The highest rate was recorded by C.F.C Bank Ltd. (733%) followed by Unga Group (500%) Dunlop Kenya Ltd. ranked third with a rate of 400%.

4.2.2 Sector Analysis

Companies quoted on the Nairobi Stock Exchange are classified into four major groups: Agricultural sector, Commercial & Services sector, Financial & Investment sector and Industrial & Allied sector.

Agricultural

Agricultural sector had a total of six bonus issue payments during the period of the study. The average bonus issue ratio came to 1 for every 1.18 shares held (85%). On the average the sector suffered a reduction in the post-bonus dividend of 3.78% with a standard deviation of 22.61%. Three companies paid less to their shareholders in the cash dividend declaration following the bonus issue. These were George Williamson, Kapachorua and Rea Vipingo Plantation whose dividends went down by 30%, 30% and 9% respectively. The other two companies, on the other hand, increased their subsequent cash dividends. Kakuzi went up by 13% and Sasini Tea and Plantation Ltd. by 13% for their 1994 issue and 20% for the 1998 issue.

Commercial and Services

This sector, like the agricultural sector, suffered a reduction in cash dividend following bonus issue. The average decrease for the sector came to 3.5% with a standard deviation of 31.86%. Of the 13 bonus issues declared in this sector during 1994 to 1998, eight were followed by improved cash dividends to shareholder, although some gains were very marginal. For four issues the shareholder received less cash dividend while one maintained the same cash dividend to shareholders after capitalisation.

The companies which increase cash dividend include Marshalls Ltd., Nation Media Group and Uchumi Supermarkets. Shareholders of A. Baumann and Co. Ltd had no change in cash dividend they received before and after capitalisation. Standard Newspapers shareholders lost out on dividend as this went down. CMC Holdings issue of 1995 was followed by an increase in dividend of 13.6% while the 1998 by a decrease of 15%. Similarly, Car and General Ltd issue of 1994 was followed by an increase of 5% while the 1996 one by a reduction of 18.2%

The bonus dividend rate for this sector averaged 74% or 1 share for every 1.35 held.

Financial and Investment

The financial sector had the highest number of bonus issue payments with twenty-three companies making bonus issues during the period covered by the study. A total of 12 companies issued bonus shares with many companies declaring it more than once. Apart from two issues where shareholder dividend remained constant, all the other issues were followed by increase in dividend. On the average the shareholders had a dividend gain of 12.5% and a standard deviation of 10.76%. Pan African Insurance maintained the same dividend after the 1995 issue but increased it by 31.08% after the 1997 issue. National Industrial Credit Bank increased dividend marginally (4%) after their 1997 bonus issue. In the previous issue of 1994 and 1996 the shareholders received the same dividend. The companies which increase dividend include Barclays Bank of Kenya Ltd, C.F.C Bank Ltd, City Trust, Diamond Trust Bank,

Housing Finance Company of Kenya, ICDC Investment, Jubilee Insurance, Kenya Commercial Bank, and Standard Bank.

The average rate of bonus issue was 66% or 1 share for every 1.52 held.

Industrial and allied

The shareholders in this sector had the highest gain in dividend with an average increase of 20.8% with a standard deviation of 33.70%. Of the 20 bonus issues declared in this sector during the period covered by the study, only three saw the shareholders loose in subsequent cash dividends. One company, East Africa Cables, maintained the same dividend to its shareholders. Otherwise the remaining 16 issues had shareholders improve their cash dividend as a result of capitalisation.

The highest increases were registered in this sector with BOC Kenya Ltd, recording a gain of 32.1%, Kenya Power and Lighting 1996 issue 120%, Unga Ltd 1997 issue 66.6%, Bamburi Cement 1995 issue 18.1%, Carbacid Investment Ltd 25.2%, Kenya National Mills 25.6%, Total Kenya Ltd 25%. Those recording moderate gains include Bamburi Cement 1996 issue 11.9%, BOC Kenya Ltd 1995 11.5%, Bamburi Cement 1997 issue 9.4%, E.A Packaging 7%, Firestone 7%, E.A Breweries 10%, Kenya National and Mills 1997 issue 16%.

The reduction in dividend was suffered by shareholders after the following issues: BAT Ltd (32.5%), Dunlop Kenya Ltd (24.6%) and Unga Group 1998 issue (9.3%). This sector had the highest rate of dividend at 104.5%, thus 1 share for every 0.96 shares held.

The significance of the difference within the four sectors was tested using the same level of confidence, and the following findings were obtained: The Z scores for various sectors were: Agricultural Sector 0.041; Commercial and Services Sector 0.04; Financial and Investment Sector –5.7 and Industrial and Allied Sector –2.77.

The decrease in Agricultural and Commercial & Services Sectors were found to be statistically insignificant. On the other hand the increases experienced in Financial & Investments and Industrial & Allied Sectors were found to be significant.

5.0 CHAPTER FIVE: - CONCLUSION, LIMITATIONS, AND RECOMMENDATIONS FOR FURTHER RESEARCH

5.1 Conclusion

The results of the survey, show that managers believe that bonus issues bring benefits to the firm. They believe that bonus issues help conserving cash. This is debatable given that companies that issued bonus shares offered higher subsequent cash dividends.

Bonus issues are used to signal that the paying firm has invested in new projects thus the need to capitalise retained earning. The need to recognise that retained earnings have been invested in permanent assets was therefore, considered as an important factor. Creating greater interest in the firm's shares is another important reason why managers issue stock dividends. It is true that shares with lower denominations appeal to wider investing community.

Broadening of shareholders base is another factor that got high ranking. Marketability of the firms' shares is increased when this is done. When retained earnings have grown disproportionately large compared to shares capital, many managers felt it is prudent to distribute it to shareholders in the form of bonus shares. And finally most managers use bonus issue to signal better future prospects.

With respect to second objective the researcher's model showed that shareholders tend to receive higher cash dividend after bonus issue.

The increased in cash dividend of 10.23% after the issue of bonus issues was found to be statistically significant.

This is in line with a study carried out by Bhalla (1987) on 50 Indian Companies where the average rate of dividend increased by 6% on capitalisation. A possible interpretation is that whenever firms make a bonus issue, the retained earnings are invested in projects that increase the future earnings of the firm. This might help explain why share prices do not adjustment fully on issue on bonus shares.

Industrial and Allied Sector had the highest increase in cash dividend (20.8%) Shareholders of companies in the financial sector also gained by receiving an average increase in dividend of (12.5%). However the agricultural and commercial and services sector experienced a decline in divided by 3.8% and 3.5% respectively. The statistical tests performed the significance of these movements found that the increases experienced in Financial & Services and Industrial and Allied sectors were significant while we decreases in Agricultural and Commercial & Services Sectors were not significant.

The findings are that a bonus issue is followed by an increase in dividends. The increase is more pronounced in Industrial and Allied

Sector, significant for Financial Sectors but not much different from zero in case of Agricultural and Commercial Sectors.

5.2 Limitations of the Study

Some Managers approached refused to give information, arguing that bonus issues was a very sensitive issue and if their views leaked into the market the performance of their shares would be affected. This suggests that some managers might be using bonus issues to manipulate share prices to their advantage.

Due to the limited time available for this research, it was not possible to carry out investigations into some of the factors, which the respondents consider important in their decision to issue bonus issues. For example, an investigation to establish if bonus issues creates greater market interest in the share, to establish if managers use bonus issues to convey information about the future prospects of their firms or to determine the effect of bonus issues on the share prices in Kenya would require that questionnaires be administered to investors.

Due to unavailability of data this study was restricted to companies quoted on the Nairobi Stock Exchange. Better knowledge would have been gained about what happens in the Kenyan Market if the sample had been drawn from both quoted and unquoted companies.

5.3 Recommendation for Further Research

Extensive research is needed on the subject of bonus issues in Kenya. This research has only looked at the important factors that influence the decisions to issue bonus shares and the gain that come with it, in terms of increased cash dividend. The areas that can be studied on this subject are various.

Further research is recommended to establish the effect of bonus issues on share prices. There is also a need to establish whether or not the views held by managers are justified and similar to those held by investors. In this regard investigations should be carried out to find out if:

- Volumes of shares traded increase as a direct result of bonus issues.
- b) The companies declaring bonus issues have had their retained earnings grow disproportionately big in relation to the capital contributed by the shareholders.
- c) Future profits grow as a result of bonus issues.

Finally a recommendation is made for inclusion of unquoted companies in a similar study.
