Accepted January 18th, 2011

This paper focuses on the joint effect of selected strategy variables on performance of large private manufacturing firms of the supply chains in Kenya. To guide the study, two specific objectives have been used namely: (1) To determine the independent effects of core competencies, strategy, strategy implementation and core capabilities on firms performance, (2) To determine the joint effect of core competencies, strategy, strategy implementation and core capabilities on firms performance. Hypotheses are tested through the analysis of both the independent and joint effects of the variables on firms performance. There is empirical evidence that the independent effect of core competencies, core capabilities, strategy, strategy implementation on firms performance is weaker compared to the joint effect of the same variables. A sample of about 52 large private manufacturing firms of the supply chains which are members of Kenya Association of Manufacturers is used.

Key words: Supply Chain Management, Manufacturing, Firms Performance, Strategy, Kenya

INTRODUCTION

In this paper the effect of selected strategy variables on corporate performance in supply chain management has been examined which includes competencies, strategy, strategy implementation, capabilities amongst many other study variables.

In formulating SCM strategy, recognition of a strategy of acquiring supplies to offset uncertainties in product supply or product distribution for an organization has been made. It involves making decisions that set and guide resource allocations for the total enterprise within the value chain.

There is a growing recognition that SCM strategies embedded in large firms are strategic sourcing, partnering, lean manufacturing, communication, postponement, responsiveness and outsourcing. These can be effective tools to satisfy demanding customers and other stakeholders. There is also increasing evidence that most of the large firms in the supply chains have a long way to go before they can realize their full potential for a truly linked SCM system (Kilpatrick et al., 2000; Harps 2000).

In this paper strategic management has been considered from the economist and management perspective, as the ability to perform better than competitors when core capabilities, core competencies, strategy and implementation are matched with performance in a SC environment. The main concern is whether a firm is capable of performing well in uncertain environment where performance indicators are not known and cannot be predicted with accuracy. The process of creating a match between competencies, capabilities, strategy and performance is the most challenging in such a scenario. Having joint SCM systems probably is an effective approach to achieving synergy.

Hamel and Prahalad (1994) provide a handbook on how to think strategically, focusing on leadership, strategy, and the changing market environment. They
state that strategy is both a process of understanding and shaping competitive forces, and a process of open-ended discovery and purposeful incrementalism. Firms need to exercise leadership and create their future to enact them by being better and especially different, change the rules of the game, reduce boundaries, blur the lines, create new industries, lead and influence, control the firm’s destiny by influencing change in the industry.

The view of scholars’ strategy is to unclean the past, have foresight, and leverage core competencies. Stable value chains do not exist. Companies need to build new profit engines, forge alliances, experiment and learn. Strategy is now more about competing for position in tomorrow’s industry than competing within today’s industry. An important implication for SCM is that business strategies are evolving and changing, making it important to constantly monitor and adjust SCM strategies, plans and measurements to ensure alignment to evolving corporate strategies. Segmentation and differentiation often require companies to support multiple strategies, which can be confusing and confounding to SC managers. SC managers pay increased attention to being effective, not just efficient. Planning follows the articulation of strategy. Planning has been defined as a deliberate process to produce systematically a preconceived outcome based on inter-linked system of decisions (Mintzberg, 1994).

Planning the design of the SCM system historically focused on inventory policy, facility location, and transport selection/routing (Ballou, 1993). Today, SC planners are also concerned with sourcing, outsourcing, and interlinked information systems that extend beyond the direct or unilateral control of the firm. These planning activities include tasks and relationships. Segmentation and mass customization strategies have added complexity. Cycle time compression and customer-mandated quality in execution have created a need for urgency and precision in planning. Several major initiatives confront planners: asset productivity, horizontal management, information substitution, linkage planning and system flexibility (Perry, 1991).

Conceptual Development
One major stream of research dominate the SCM strategy literature: the effect of competencies, capabilities, strategy formulation and implementation on firms performance. Literature have been reviewed in line with the schematic framework (figure 1).
Emphasis has been put on how variables interact in the SCs of large manufacturing firms. The test of the variables has been done in two phases. Phase one provides a roadmap where independent variables of core competencies, core capabilities, strategy, strategy implementation, independently interact with firms performance. These variables have been tested and their relationship determined using advanced statistical techniques.

In phase two, the joint effect of core competencies, core capabilities, strategy, strategy implementation, on firms performance have been tested. A feedback loop is provided to evaluate the performance measurement. In essence, the study sought to establish the additive effect of the study variables jointly if any on firms performance across the SC as opposed to their independent effect. The two phases were necessary to compare the correlation of variables in accordance with the objectives of the study.

The current research developed a mathematical model of SCM based on the study hypothesis. In this paper null hypotheses have been explored to support the study:

Variables with independent effect

H₁  Core competencies have no independent effect on firms performance.
H₂  Core capabilities do not have independent effect on firms performance.
H₃  Strategy does not have independent effect on firms performance.
H₄  Strategy implementation does not have independent effect on firms performance.

Variables with joint effect

H₅  The joint effect of core competencies, core capabilities, strategy and strategy implementation on firms performance is not greater than the sum total of the independent effects of the same variables on firms performance.

The mathematical model was used to analyze the performance of large private manufacturing firms from antecedent of linkages between SC core competencies, SC strategy, the strategy implementation process, SCM core capabilities and firms performance, using linear regression analysis. The regression model assumes the following equations:

Hypothesis 1
Firms performance = \( f \) (constant term + core competencies + error term)
\[ P = \alpha + \beta_1X_1 + \epsilon \]

Hypothesis 2
Firms performance = \( f \) (constant term + core capabilities + error term)
\[ P = \alpha + \beta_2X_2 + \epsilon \]

Hypothesis 3
Firms performance = \( f \) (constant term + strategy + error term)
\[ P = \alpha + \beta_3X_3 + \epsilon \]

Hypothesis 4
Firms performance = \( f \) (constant term + strategy implementation + error term)
\[ P = \alpha + \beta_4X_4 + \epsilon \]

Hypothesis 5
Firms performance = \( f \) (constant term + core competencies + core capabilities + strategy + strategy implementation + error term)
\[ P = \alpha + \beta_1X_1 + \beta_2X_2 + \beta_3X_3 + \beta_4X_4 + \epsilon \]

Where
Dependent variable is Firms performance and is denoted by \( P \)
Independent variables are:
\( X_1 \) - Core competencies of SC,
\( X_2 \) - Core capabilities of SC,
\( X_3 \) - Strategies used in SC,
\( X_4 \) - Implementation of SC strategy,
\( \alpha \) – Constants term,
\( \beta \) – Beta coefficients,
\( \epsilon \) – Error term.

The model presents a simplified approach of the linkage between competencies, strategy, implementation of strategy, capabilities and firms performance. This model explains the effect of the selected strategy study variables on performance in the work environment of the manufacturing sector in a developing economy like Kenya.

Effect of selected Strategy Variables on firms performance

The independent effect of core competencies, strategies and strategy implementation process and core capabilities on firm’s performance may also create competitive advantage for a firm, but nevertheless, over time may be imitated by competitors.

They may be more robust and difficult to imitate if they relate to the firm’s value chain and supply and distribution chains (Johnson & Scholes, 1999). It is the management of these linkages which provide leverage and levels of performance that is difficult to match.

The major variables of SCM that affects firms performance independently are core competencies, strategy, strategy implementation and core capabilities. Stalk et al (1992) underscore the importance of this linkage. They observe that competencies and capabilities represent two different but complementary dimensions of an emerging paradigm for firms strategy.

Competencies relate to skills, knowledge and
technological know-how that give a special advantage at specific points of the value chain, which in combination with strategy, form core capability of a firm. This in turn enhances firms performance, creates synergy and competitive advantage. Indeed, increased outsourcing to fewer suppliers managed using collaborative techniques can be characterized as a means of achieving the adventures of SCM without owning the means of production and the inherent risks of advances in technology or changes in law (Rich & Hines, 1997). The pressure from customers and financial markets has increased managerial recognition that companies cannot be effective by trying to be all things to all customers and should focus on limited set of core competencies (Fine, 1999; Cox, 1999). The more a company concentrates on core competencies, the more it believes that other firms are better placed to manage some parts of the company thereby raising the profile of the SCM (Das & Narasimhan, 1999, Cox, 1999). Fine (1999) considers effective SC to be the ultimate core competence and is critical to company successful performance (Quinn, 2000). Core capabilities, therefore, are the most distinctive resources a company possesses and the most difficult to imitate when effectively matched to strategic targets in the value chain that begins and ends with the company’s key stakeholders. **Figure 2**

In addition to the management of the above linkages, competitive advantage may also be gained by the ability to complement or co-ordinate the firm’s own activities with those of suppliers, channels or customers through SCM best practices (Porter, 1985). This attempts to improve performance through ownership of more parts of the value system, making more linkages external to the organization. The linkages in the SCM therefore form an integral part of this paper.

The linkage between core competencies and performance is widespread and is not specific to any industry. The force of core competencies is felt as decisively in service as in manufacturing industry. Prahalad and Hamel (1990) posits that competencies are the roots of competitiveness. They observe that in the short run, a company’s competitiveness derives from the price/performance attributes of current products. In the long run, competitiveness derives from an ability to build,
at lower cost and more speedily than competitors, the core competencies that spawn unanticipated products. The real sources of competitive advantages are to be found in management’s ability to consolidate corporate-wide technologies and production skills into competencies that empower individual businesses to adapt quickly to changing opportunities thus enhancing corporate performance.

Johnson and Scholes (1999) observe that the ability of an organization to co-ordinate the activities of specialist teams or departments may create competitive advantage and improve performance by improving value of money in the product or service industry. Specialization of roles and responsibilities in most organizations is one way in which high levels of competence in separate activities and divisions is guaranteed.

The management of strategy independently in the value chain could enhance performance in a number of ways. For instance, there may be important linkages between a primary activity and a support activity and between different support activities. Porter (1985) describes how selected strategy variables in the value chain link together to enhance corporate performance by creating value and customers satisfaction. Figure 3

Porter (1980) presents an approach to strategy, combined with a tool-kit for practitioners. He describes five forces that drive industry competition: potential entrants, suppliers, buyers, industry competitors, and substitutes. He reports entry barriers to be scale, differentiation, capacity requirements, switching costs, distribution channel access, raw material access, government policy, and retaliations.

He describes exit barriers as being economic, strategic and emotional. All these factors should be considered in evaluating strategic choices. He imparts three generic strategies for competition: low-cost, differentiation, and focus. He warns firms against getting “stuck in the middle” with a half-hearted mix of options, not emphasizing one of the three strategies. He states that the strategic choices cannot be pursued simultaneously, but they can be pursued sequentially, as opportunities dictate. Porter (1980) describes four diagnostic components to developing strategy: future goals that drive it, current strategy (or what the firm is doing and can do), assumptions about itself and the industry and capabilities. Porter (1980) recommends a strategy to seek the most favourable buyer; build up buyer switching costs; and reduce costs to switch from suppliers.

Other studies which have been examined in this paper have also discussed the effect of selected strategy variables on performance, and a number of conclusions drawn. Caeldries and van Dierdonck (1988) did a study on effect of strategy and performance of 82 Belgian firms. They established the relationship between strategy and performance. They concluded that strategy enables the firm to strengthen its competitive position externally; they further observed that for the internal functioning of the organization, strategy facilitates the linkage and co-
ordination of members’ behaviour.

According to Prahalad and Hamel (1990) and Barney (1991) they define core capabilities as complex bundles of skills and collective learning, exercised through organizational processes that ensure co-ordination of functional activities. In their study they concluded that strategic importance of core capabilities lies in their demonstrated contribution to sustainable competitive advantage and superior profitability. Varadarajan et al (1995) in another study of large firms in UK found that the linkage of key variables within SCM, can lead to competitive advantage by enabling the partner to perform various value chain activities better and at lower cost and/or in a way that leads to differentiation.

Stanley and Magnan (2001) in an examination of strategy in the large private manufacturing companies in US, realized that SCM is different from most commercial studies in that it is inherently cross-functional and inter-organizational. Most SCM strategies are not owned by the purchasing organization but other organizations within the SC that also provide the required linkages towards the overall organizational performance.

Another study by David (1997) indicates that sound SCM policies, proper resource allocation, good corporate culture, proper management of conflict and resistance to change, are key considerations in strategy implementation process and may act as an impediment to successful implementation if not checked.

Measure of Firms Performance in SCM
Measurement of performance of large firms is based on both quantitative and qualitative performance indicators. The SC efficiency and effectiveness are two major concerns for SCM scholars. This will be discussed in the subsequent sub-sections.

Quantitative Performance Measures

They made an important distinction between effectiveness determinants (that is, customer satisfaction) and effectiveness dimensions, such as timeliness and accuracy. Harrington, Lambert and Christopher (1991) provided a formal vendor performance measurements model that used defined criteria and weighted scores to assess the performance of suppliers. The model was tested and successfully implemented.

Chow, Heaver, and Henriksson (1994) provide a summary of SCM performance measurement literature published in five leading SCM journals between 1982 and 1992 focusing on accounting techniques. Generally, the literature found that firms tend to focus on their own internal performance, and are especially concerned with efficiency measures. Discussions of ‘SC performance measures were noticeably absent. Additional other aspects quantitative measures of SCM with accounting measures (Kaplan, 1984; Eccles & Pyburn, 1992; Speh & Novack, 1995), cost and effect (Kaplan & Cooper, 1997), balanced scorecards (Kaplan & Norton, 1992), economic value added and shareholder value (Glassman & Stern & Stewart Co., 1997), the total cost/value model (Cavinato, 1992), linkages to financial statement (Cavinato, 1989), the stakeholder approach (Atkinson et al., 1997), transaction cost analysis (Rindfleisch & Heide, 1997) and the economics of lead-time reduction (Wouters, 1991).

Qualitative Performance Measures
Qualitative measures in SCM are the second major area covered by the literature. Topics include strategic performance (Chakrarvathy, 1986), continuous improvement performance measures (Fortuin, 1988), process controls (Novack, 1989), design (Stevens, 1989; Perry, 1991) and flow analysis (Scott and Westbrook, 1991; Farris, 1996), quality control systems (Hillman et al., 1990) and quality programmes in SCM (Read et al., 1991), outsourcing (Aertsens, 1993; Foster, 1998) and (Fawcett and Clinton, 1996).

Customer service has become a crucial measure of competitiveness in markets throughout the world. As competition gets more intense, service quality is seen as a primary determinant of overall customer satisfaction. The need to achieve service excellence in markets characterized by shrinking margins and tight budgets has created a powerful challenge for SCM. The challenge is to balance these operational realities with the need for quality customer service. Service quality can be managed effectively, even when market conditions are difficult and resources are limited, if the organization can focus on a limited number of high-priority SCM service features (La Londe & Cooper, 1988). One study presents a customer’s perspective on product and information flows (Rhea and Shrock, 1987b). Another study presents a technique for the evaluation and management of customer service quality (Harding, 1998). Customer satisfaction has been shown to depend directly on performance measurement of effective order fulfillment (Davis, 1998).

Benchmarking topics abound, especially in the trade press. Most SC managers want to have a guide to what to measure, and to compare their own operational performance to that of their competitors, or to a “best-in-class” model. Various benchmarking articles are concerned with the values of performance measures and not the numerators and denominators of them, leaving the comparability and validity of the values at question. One notable exception to the emphasis on content rather than process benchmarking is found in the efforts of the SC Council (Pittiglio et al., 1994).
They place a high priority on identifying causal linkages between and amongst variables. The positivists tend to assume that a single, objective reality exists independent of what individuals perceive; they share the fundamental belief that the material world of tangible objects does not exist unperceived. They share the fundamental belief that...
core capabilities, though significant, have low explanatory power on corporate performance which implies that hypothesis two did not accurately predict the outcome of the study, leading to rejecting the null hypothesis.

**H3: Strategy does not have independent effect on corporate performance**

According to the analysis, there is indication that 34.3 per cent of the variations in corporate performance is explained by strategy, with an accuracy of 99 per cent, nearly 65.7 per cent is explained by other factors. The effect of strategy, though significant, has low explanatory power on corporate performance, which implies that the hypothesis did not accurately predict the outcome of the study, leading to rejecting the null hypothesis.

**H4: Strategy implementation does not have independent effect on corporate performance**

The results indicate that 11.8 per cent of the variations in corporate performance is explained by strategy implementation, with an accuracy level of 99 per cent, nearly 88.2 per cent is explained by other factors. The effect of strategy implementation, though significant, has low explanatory power on corporate performance. This suggests that the hypothesis did not accurately predict the outcome of the study, leading to rejecting the null hypothesis.

These findings are similar to studies done by other scholars where emphasis was more on the independent effect of variables on corporate performance. Chandler (1962) for example, looked at strategy and structure. Andrews (1971) did a similar study. Boeker and Goodstein (1991) studied the relationship between environment and corporate performance. In all these studies, it was established that various variables have significant effect independently on performance.

**The objective Two**

To determine the joint effect of core competencies, core capabilities, strategy and strategy implementation on corporate performance. This was addressed by testing hypothesis five using multiple regression analysis. Table 2

**H5: The joint effect of core competencies, core capabilities, strategy and strategy implementation on corporate performance is not greater than the sum total of the independent effects of the same variables on corporate performance.**

The results show that jointly the variables explain 52.2 per cent of the variation in corporate performance with accuracy of 99 per cent, 47.8 per cent is explained by other factors. There is evidence that the joint effect of the variables is greater compared to their independent effect. Furthermore, the joint effect is significant with a high explanatory power on firms performance; we therefore reject the null hypothesis.

**DISCUSSION AND CONCLUSIONS**

In this paper a summary of findings of the study is provided, discussion and conclusions drawn.

**Summary and Conclusions**

This part provides a summary and conclusions on the findings as follows: (1) there is evidence that the independent effects of core competencies, core capabilities, strategy, strategy implementation is relatively weaker compared to their joint effect. In contrast, previous studies did not address the effect of these variables jointly; they only considered the measurement of competencies, strategies, capabilities independently on performance (Caeldries & van Dierdonck 1988; Johnson & Scholes 1999; Day 1994; Stanley & Magnan 2001).

This study has, however, provided an outcome where the effect of SCM variables can be measured jointly against firms performance in the large private manufacturing SC firms in Kenya. The study has made attempts to establish the synergistic effect of the selected strategy variables. From the theoretical perspective, these variables can create competitive advantage in the value chain. Porter (1985) in addition to the management of the above linkage, posits that competitive advantage may also be gained by the ability to complement or coordinate the organizations’ own activities with those of suppliers, channels or customers through strategies used in SCM. (2) There is further evidence that SCM provides an environment where core competencies, strategy and strategy implementation process, core capabilities can be linked effectively within the value chain to enhance corporate performance, (3) the joint effect of core competencies, core capabilities, strategy and implementation has influenced firms performance by creating synergy in most of the large manufacturing organizations surveyed in the private sector in Kenya. As SCM variables, they support other findings in strategic management Smit et al (1993) where selected strategy variables has been used deliberately to achieve an enterprises mission and objectives by reconciling its resources with opportunities and threats in the business environment, (4) there is universal consensus that strategy formulation and implementation are fundamental in setting direction and objectives for the firm. This is critical to this paper which supports Ackhoff’s 1981

The model was tested at 95 per cent confidence level.
findings, who posits that environment is important to strategy formulation and that strategy must be well-articulated. This is necessary to manage the dynamic changes within the environment, (5) the findings support the study of Stanley and Gregory (2001) that the implementation of strategy in large private manufacturing companies is inherently cross-functional and inter-organizational. Most of SCM strategies are not owned by individual firms but also other organizations within the SC that also provide the required linkages towards the overall corporate performance of the manufacturing industry. They play a crucial role in the implementation of SCM strategies within the value chain process.

To make the economy more vibrant and to improve productivity, proper corporate structure and governance need to be put in place where SCM competencies, strategy, capability, can be used to create synergy. In effect, no single variable can effectively influence firms performance. An enabling environment is needed for the variables to operate jointly in order to improve socio-economic development for a country like Kenya and spur economic growth, the study concludes.

ACKNOWLEDGEMENT
I am pleased to acknowledge the contribution of Prof. Peter K’ Obonyo, Dr. Gitumo Wainaina, Dr. Martin Ogutu and Prof. Ganash Parasad Pokhariyal from the school of Business University of Nairobi for their valuable contribution to the previous drafts and ultimately in providing guidance and counseling to produce a paper of such a magnitude.
