**JULY 2013**

## DECLARATION

I the undersigned, declare that this thesis is my original work and to the best of my knowledge has not been presented for the award of a degree in any other university.

**Signature**.....

**Date**.....

**Candidate:** Milugo Trizah Koyi

**Reg No:** I56/64074/2010

This thesis has been submitted with our approval as supervisors.

**Signature**.....

**Date**.....

Dr. Leonida Kerubo Omosa,  
Department of Chemistry,  
University of Nairobi.

**Signature**.....

**Date**.....

Prof James Ochanda,  
Center for Biotechnology and Bioinformatics,  
University of Nairobi.

**Signature**.....

**Date**.....

Dr. Fred Wamunyokoli,  
Department of Biochemistry,  
Jomo Kenyatta University of Agriculture and Technology.

**Signature**.....

**Date**.....

Dr. Julius Oyugi,  
Department of Medical Microbiology, Institute of Tropical and Infectious Diseases,  
University of Nairobi.

## **DEDICATION**

This thesis is dedicated to my parents, John Milugo and Hellen Milugo for playing a vital role in my upbringing and encouragement to pursue my Master in Science (MSc.) studies.

## **ACKNOWLEDGEMENT**

My most sincere gratitude goes to my supervisors, Dr. Leonidah Kerubo, Dr. Fred Wamunyokoli, Dr. Julius Oyugi and Prof. James Ochanda for their guidance, excellent advice and patience throughout the period of my research work. I will forever be grateful to Bethwel Owuor for always ensuring that I had enough plant materials for my research work.

I acknowledge the German Academic Exchange Services (DAAD) and Gandhi Smarak Nidhi Fund for the scholarship award for my MSc studies. I sincerely thank Dr. Wallace Bullimo for giving me the opportunity to undertake training on tissue culture in his laboratory, and together with Prof. Philip Nyaga for their assistance with the cell lines.

I greatly appreciate Drs. Isabella Ocholla and Joel Ochieng for their support and encouragement throughout the course of my study. Many thanks go to the technical staff of the Department of Medical Microbiology, Institute of Tropical and Infectious Diseases, and the Natural Product group, Department of Chemistry, University of Nairobi. I also commend the assistance by my colleagues at the Center for Biotechnology and Bioinformatics (CEBIB).

Finally, I thank my family for financial and moral support throughout my study. Their love and care gave me the will to carry on to the end.

## ABSTRACT

This study had the aim of phytochemically evaluating the usefulness of two plants (*Moringa oleifera* and *Rauwolfia caffra*), used in traditional health care to manage cancer and diseases related to oxidative stress. To achieve this, the leaves of *M. oleifera* and the leaves and stem bark of *R. caffra* were extracted with different solvent systems and subjected to Radical Scavenging Activity (RSA) assay to determine the level of antioxidant activity. Establishing the antioxidant activity of the extracts of the two plants is important since strong antioxidants are normally associated with the prevention of cancer.

RSA was assessed using 1, 1-diphenyl-2-picrylhydrazyl (DPPH) method and the commercially available quercetin was used as a positive control. The 50 % CH<sub>2</sub>Cl<sub>2</sub>: MeOH extracts of the stem bark of *R. caffra* exhibited the highest RSA of 96.03 % at 0.2 mg/ml while the MeOH extract of the leaves of *M. oleifera* showed RSA of 83.84 % at 0.2 mg/ml. The *R. caffra* stem bark fractions obtained by fractionation of the total extract (CH<sub>2</sub>Cl<sub>2</sub>: MeOH; 1:1) revealed possible antagonistic effect in at least two classes of secondary metabolites: co-occurrence of alkaloids and saponins reduced antioxidant activity (all phytochemicals = 58 %; alkaloids only = 63 %; alkaloids plus saponins = 15 %). However, synergistic activity was observed for a combination of steroids, terpenoids and cardiac glycosides, but without alkaloids (82 %).

Anti-proliferative activity was assessed using crystal violet assay where human hepatocellular carcinoma (Liver cancer; Hep-G2) and rhabdomyosarcomas (Muscle cancer; RD) were used as model cell lines, while Vero cells were used as control, and to test for possible cytotoxicity to normal cells. The MeOH extract of the leaves of *M. oleifera* displayed significant anti-proliferative activity ( $p < 0.05$ ) against Hep-G2 and RD cell lines with limited activity on Vero cells. Comparatively, proliferation of RD cell lines was more affected than Hep-G2. The 50 % MeOH/CH<sub>2</sub>Cl<sub>2</sub> extract of the stem bark of *R. caffra* did not show significant activity against proliferation of RD and Hep-G2 cells, but it exhibited activity against proliferation of Vero cells.

Overall, *M. oleifera* leaf extracts were less toxic and displayed anti-proliferative activity while extract of the stem bark of *R. caffra* was not target specific. However, the latter exhibited significant antioxidant activity. The usefulness and risk levels associated with drumstick and

quinine tree; plants used in traditional medicine to manage cancer and diseases related to oxidative stress, require further investigation as the solvent systems used in this study, may not exactly mirror those used by traditional healers. Phytochemicals have been shown to act in a solvent specific manner.

# CHAPTER ONE

## INTRODUCTION

### 1.0 GENERAL

Cancer remains a major global health burden and is currently ranked as the third leading cause of death worldwide after cardiovascular and infectious diseases (WHO, 2013). A recent situational analysis showed cancer cases in Kenya to stand at 22,000 deaths annually (Ministry of Public Health and Sanitation and Ministry of Medical Services, Kenya 2011). Lack of effective chemotherapeutic drugs for cancer treatment may be a major contributor to the high fatality rate. Most drugs that are currently used in cancer treatment and management are costly and their success rates are low. For instance, chemotherapy which is the most common mode of cancer treatment today involves the use of chemotherapeutic drugs which tend to kill normal and cancerous cells alike, thus causing severe side effects (National Cancer Institute, USA 2011). Such challenges have made it necessary to continuously search for alternative drugs for cancer management. A number of compounds with anticancer activity have previously been isolated from plants and synthesized for use in contemporary medicine, indeed most promising anticancer drugs contain a bioactive compound that can be traced to plants (Heinig and Jennewein, 2009). Kenya has a wealth of indigenous knowledge in traditional medicine; for instance, the Kuria community uses certain plants (*Moringa oleifera* and *Rauwolfia caffra*) in traditional management of multiple tumors (Owuor B, personal communication). As such, it is possible that these plants contain bioactive molecules that can suppress tumor. This study investigated the anticancer properties of *Moringa oleifera* and *Rauwolfia caffra*.

### 1.1 Cancer prevalence and therapy

Cancer is a class of disease that is characterized by uncontrolled division of cells and is one of the most common diseases with a high incidence and mortality rate globally (World Health Organization (WHO), 2013). Current statistics indicate that over 7.9 million people succumb to cancer related illness every year and this is expected to rise to 13.1 million by 2030 if immediate interventions are not put in place (WHO, 2013). To lower the mortality rate of cancer, several cancer treatment methods such as chemotherapy, radiation therapy and surgery have been developed. In chemotherapy, drugs are designed to arrest the cell cycle or cause apoptosis of

cancerous cells. However, their mode of action involves targeting rapidly dividing cells, hence they are known to cause severe side effects to some cells in the body such as; bone marrow cells, immune cells and hair follicle cells that portrays similar characteristics (National Cancer Institute, USA 2011). Radiation therapy works by damaging the deoxyribonucleic acid (DNA) of the cancerous cells, but this may also damage the DNA of adjacent normal cells leading to adverse side effects (National Cancer Institute, USA 2011). Surgery is yet another form of cancer treatment; the kind of surgery varies depending on the type of cancer and the patients' health (National Cancer Institute, USA 2011).

## **1.2 Oxidative stress and antioxidants**

Oxidative stress is a condition that occurs when the level of free radicals in the body increases beyond the scavenging ability of the antioxidants in the body, resulting in severe consequences such as DNA damage, protein oxidation or lipid peroxidation (Paliwal *et al.*, 2011; Turrens, 2003). Free radicals are unstable and very reactive molecules that are produced as byproducts of normal biological processes such as mitochondrial oxidative phosphorylation, prostaglandin synthesis and phagocytosis (Halliwell, 1989), as well as on exposure to environmental factors such as pollution, radiation and cigarette smoke (Hamid *et al.*, 2010). Therefore, the human body is usually exposed to plenty of free radicals that may interfere with the functioning of the cells. The body has developed natural antioxidant defense mechanisms to help guard against oxidative stress (Halliwell, 1989; Paliwal *et al.*, 2011).

Antioxidants are molecules with high affinity for free radicals and they are of two types; natural and synthetic antioxidants. Natural antioxidants such as vitamin A (**1**) (Figure 1), C (**2**) (Figure 1), and E (**3**) (Figure 1), are obtained from herbs (Paliwal *et al.*, 2011), grains (Hodzic, 2009), spices (Ghasemzadeh and Rahmat, 2010; Maizura and Wan Aida, 2011), fruits (Ramamoorthy and Bono, 2007) and vegetables (Kunyanga *et al.*, 2012) while synthetic antioxidants such as Butylated Hydroxytoluene (BHT) (**4**) (Figure 1), and propylgallate (**5**) (Figure 1), are commercially produced. Synthetic antioxidants are associated with carcinogenesis whereas natural antioxidants are considered safe and have been isolated and used as ingredients in dietary supplements for management of various diseases such as cancer, coronary heart diseases and many others (Hamid *et al.*, 2010).

**Figure 1:** Structure of compounds with antioxidant activity. Vitamin A (1), C (2) Vitamin E (3), BHT (4) and Propylgallate (5)

### **1.3 PROBLEM STATEMENT**

Medicinal plants are commonly used by many communities across the world to treat various ailments; however, there is very little scientific evidence to verify the efficacy of bioactive compounds present in these plants. This is because ethno-medical knowledge is normally held in secrecy by traditional herbalists, making it difficult to conduct any scientific investigations. The Kuria community of Kenya for instance, uses certain medicinal plants to manage tumor and related ailments. Despite such promise in cancer treatment, the biochemical mode of action of these plants remains unknown. As such, it is difficult to design a novel anticancer drug from the extracts of these plants since doing so requires background knowledge of the identity, composition and structure of the bioactive phytochemicals. Thus, assessing the efficacy of bioactive compounds present in medicinal plants and determining their specificity against certain cancer types is essential. To facilitate an immediate uptake of these results by pharmaceutical industries, the active pharmaceutical compounds present in these plants needs to be isolated and described. Further, assessment on side effects and biosafety of the pure compounds is also required.

## **1.4 RESEARCH OBJECTIVES**

### **1.4.1 General objective**

To biochemically assess the usefulness of phytochemicals present in drumstick and quinine tree in management of cancer and other diseases related to oxidative stress.

### **1.4.2 Specific objectives**

- I. To determine whether drumstick and quinine tree can be used to suppress cell proliferation and kill cancerous cells.
- II. To assess the level of risk associated with the use of drumstick and quinine tree in cancer management in traditional medicine.
- III. To understand the mechanism of action of active compounds from the two plants by identifying major phytochemicals present.

## **1.5 JUSTIFICATION**

Exploring locally available therapies for management of chronic diseases such as cancer should be encouraged since most currently available anticancer drugs are costly and have low efficacy. In other regions of the world, search for new therapeutic alternatives for treatment of diseases such as cancer have focused on plants. Kenya is home to great biological diversity including indigenous plants from which potential lead structures for use in formulation of novel drugs can be obtained. Drumstick (*M. oleifera*) and quinine tree (*R. caffra*) are plants used in traditional medicine to manage cancer and diseases related to oxidative stress such as rheumatism, inflammations and diabetes. These diseases are usually managed in formal hospitals but people in many parts of the world are now increasingly getting attracted to herbal medicine. These are cost effective, easily available and acceptable to local communities. It is risky; however, if these herbs don't really work yet people suffering from various tumor-related ailments fail to seek formal medical attention. It needs to be established scientifically that these herbs indeed have bioactive compounds that can cure cancer. There is also need for safety assessments to evaluate if any risk is associated with their consumption. Such knowledge will inform pharmaceutical industry on the medicinal value of these plants, and will also validate indigenous knowledge as valuable resource for medicine and pharmaceutical explorations.

## **1.6 HYPOTHESIS**

Drumstick (*M. oleifera*) and quinine tree (*R. caffra*) have phytochemicals with tumor suppressing ability.

## CHAPTER TWO

### LITERATURE REVIEW

#### 2.1 Botanical information

##### 2.1.1 The family *Moringaceae*

Drumstick (*M. oleifera*) also known as the horse-randish tree, belongs to the family *Moringaceae*; a monogeneric family that has thirteen species consisting of shrubs or trees (Navie and Csurhes, 2010). The members of this family are recognized by their compound leaves which have a unique unpleasant smell when crushed. The flowers have five stamen held on one side of the flower while the fruits contain winged seeds and are often pollinated by wind, bees and birds (Navie and Csurhes, 2010). They can be used as food, fodder, or as ingredients in traditional medicine (Fahey, 2005; Navie and Csurhes, 2010).

##### 2.1.1.1 The genus *Moringa*

The genus consist of the following species; *M. arborea* (endemic to Kenya), *M. borziana*, *M. concanensis*, *M. drouhardii*, *M. hildebrandtii*, *M. longituba*, *M. oleifera*, *M. ovalifolia*, *M. peregrine*, *M. pygmaea*, *M. rivaie*, *M. ruspoliana* and *M. stenopetala* (Navie and Csurhes, 2010). The species are further categorized into three groups; the first group “bottle neck tree” consists of four species of trees characterized with swollen trunks and radially symmetrical flowers. The second group “tuberous clade” consists of six species with thick and fleshy tuberous roots and the third group “slender tree clade” consists of three species with slender-trunked trees and bilaterally symmetrical flowers (Navie and Csurhes, 2010). *M. oleifera* which is the most widely cultivated species belongs to the “slender tree clade”.

##### 2.1.1.1.1 Ethno-medicinal uses of the genus *Moringa*

Plants in the genus *Moringa* have been used by many communities in the world to manage a number of ailments as listed in table 1.

**Table 1:** Ethno-medical uses of the genus *Moringa*

### 2.1.1.2 *Moringa oleifera*

Drumstick (*M. oleifera*) also known as Miracle tree in English and Mronge in Kiswahili is a fast growing evergreen tree that grows to the height of 15 meters. It has swollen underground rootstocks that have a taste of horse-radish hence, its normally called horse-radish tree (Navie and Csurhes, 2010). It produces large elongated capsules containing numerous seeds; these seeds contain large quantities of oil which are used as medicine (Table 1), fuel, perfume or as lubricants (Fahey, 2005; Navie and Csurhes, 2010). Although *M. oleifera* is native to the Himalayan tracts of India, Pakistan, Bangladash and Afghanistan, it has currently become naturalized in many locations in the tropics (Fahey, 2005). In Kenya for instance, it is found in Malindi, Likoni, Kitui, Kibwezi (Muluvi *et al.*, 1999), Kuria and Suba counties (Owuor B, personal communication).

**Figure 2:** A typical *M. oleifera* tree growing in a natural environment. Photo by Price, 2007

### **2.1.2 The family *Apocynaceae***

Quinine tree (*R. caffra*) belongs to the family *Apocynaceae* which is a family of flowering plants that consist of 164 genera and 1,500 species most of which are herbs, trees, lianas and shrubs. Most of these plants are known to be poisonous and to produce milky latex when injured (Watson and Dallwitz, 1992). The family is divided into five subfamilies; *Apocynoideae*, *Rauwolfioideae*, *Asclepiadoideae*, *Periplocoideae* and *Secamonoideae*. Plants of this family have flowers that are bisexual while the leaves are usually evergreen, alternate or opposite, simple or whorled and lacks stipules. The seeds are flat and winged and may have a tuft of hairs at one end (Watson and Dallwitz, 1992). The plants can be used as food, fodder, ornaments, medicine or as arrow poison (Watson and Dallwitz, 1992).

#### **2.1.2.1 The genus *Rauwolfia***

The genus *Rauwolfia* is named after Leonhard Rauwolf a German physician who was specialized in plants collection (Orwa *et al.*, 2009). This genus has 42 species most of which are poisonous hence their use as medicinal plants is highly discouraged ([www.prota.org](http://www.prota.org)). Examples of species in this genus are; *R. serpentina*, *R. caffra*, *R. vomitoria*, *R. stricta*, *R. media* and *R. mombasianna* which is native to Kenya ([www.prota.org](http://www.prota.org)).

##### **2.1.2.1.1 Ethno-medical uses of the genus *Rauwolfia***

The plants in the genus *Rauwolfia* are characterized by poisonous shrubs and small trees that are rich in alkaloids; basic organic substances containing at least one nitrogen atom in their structure (Hamid *et al.*, 2010). Plants in this genus have been used extensively by many communities in the world to treat a number of ailments, their ethnobotanical uses are described in table 2.

**Table 2:** Ethno-medical uses of the genus *Rauwolfia*

### 2.1.2.2 *Rauwolfia caffra*

Quinine tree (*R. caffra*) also known as mwembe mwitu or mkufu in Kiswahili is an evergreen tree that grows to the height of 35 meters, forming a dense crown. It has simple leaves which are shiny green on the upper surface but paler on the lower surface. The flowers are bisexual and have a cup shaped calyx with the anthers slightly above the stigma (Orwa *et al.*, 2009). *R. caffra* grows at altitudes of 0 to 1,500 meters and is usually found along streams or in swampy forest. In Kenya, *R. caffra* is commonly found along the coastal region (Orwa *et al.*, 2009).

**Figure 3:** A typical *R. caffra* tree in natural environment. Adopted from [www.prota.org](http://www.prota.org).

### 2.1.3 Biological activity of extracts and compounds from *M. oleifera*

Drumstick is used in traditional medicine to treat respiratory tract infections (Mehta and Agrawal, 2008), bacterial and fungal infections, and sexually transmitted diseases (Rahman *et al.*, 2009). The leaves have strong antioxidant activity (Chumark *et al.*, 2008; Khalafalla *et al.*, 2010) while the seeds contains high levels of monosaturated oils and proteins, hence, the plant is commonly given to infants and nursing mothers suffering from malnutrition to boost their immune systems (Fahey, 2005; Tsaknis *et al.*, 1999). The seeds contain compounds of pharmaceutical importance and this might explain the extensive use of *M. oleifera* seeds in the treatment of various diseases (Table 1). Additionally, the seeds are used as water disinfectant since they contain polypeptide molecules that act as cationic polymers (Lantagne *et al.*, 2008).

Informed by its wide traditional medicinal uses, chemical investigations have been carried out on *M. oleifera* and several bioactive compounds isolated and identified: Examples of such compounds include; the antioxidant kampeferol (**6**) (Figure 4) which was isolated from the leaves (Bushra and Anwar, 2008), and pterygospermin (**7**) (Figure 4) a potent antibiotic and antifungal agent isolated from the flowers and roots (Horwath and Benin, 2011; Navie and Csurhes, 2010). The root bark contains very toxic alkaloids and is rarely used for medicinal purposes (Navie and Csurhes, 2010).

**Figure 4:** Structure of bioactive compounds from *M. oleifera*; kampeferol (**6**), pterygospermin (**7**).

#### 2.1.4 Biological activity of extracts and compounds from *R. caffra*

Previous studies (e.g Erasto *et al.*, 2011; Gbonjubola, 2010; Nasser and Court, 1984) have revealed the presence of pharmacologically important compounds from *R. caffra*. For instance, alkaloids from the root extracts have been shown to have a very strong antimicrobial and antioxidant activity (Erasto *et al.*, 2011). Macrocaffrine (**26**) and yohimbine (**27**) are compounds of medicinal importance found in *R. caffra* (Ohba and Natsutani, 2007). Yohimbine (**27**) for instance, is a potent antidepressant used in treatment of hypertension (Marion, 1952).

**Figure 5:** Structures of bioactive compounds from *R. caffra*; macrocaffrine (**26**); yohimbine (**27**)

#### 2.1.5 Phytochemistry of the genus *Moringa*

The genus *Moringa* is known to contain a number of phenolic compounds as shown in table 3 and the respective structures are found in **Appendix 1**. The basic structure of phenols consists of a hydroxyl group attached to a benzene ring (**8**).

**Table 3: Compounds previously described in *Moringa* species**

Compounds	Source	Reference
<b>Phenols</b>		
Amino methoxysulfinyl pentasilfide ( <b>9</b> )	<i>M. oleifera</i>	Faizi <i>et al.</i> , 1998

Kaempferol 3,7-diglycopyranosyl ( $\beta$ -D-glucopyranosyl-(1-2) - ( $\alpha$ rhamnopyranosyl-(1-6)- $\beta$ -d-glucopyranoside), 7-O- $\alpha$ -L-rhamnopyranoside) ( <b>6</b> )		Faizi <i>et al.</i> , 1995; Bushra and Anwar, 2008
Rhamnose; $\alpha$ -l-pyranose-form, Ph glycoside ( <b>21</b> )		Francis <i>et al.</i> , 2004
3-(2-Heptenyloxy)-1,2-propanedioal-3-undecanoyl ( <b>22</b> )		Faizi <i>et al.</i> , 1994; Faizi <i>et al.</i> , 1998
Niazidin ( <b>24</b> )		Francis <i>et al.</i> , 2004
4',5,7-Tryhydroxyflavonon 5- Me ether, 4'-O-( $\alpha$ -L-rhamnopyranosyl-(1-2)- $\beta$ -D- glucopyranoside), 7-O- $\beta$ -D- glucopyranoside ( <b>25</b> )		Albach and Redman, 1969

### 2.1.6 Phytochemistry of the genus *Rauwolfia*

The genus *Rauwolfia* is known to contain a number of alkaloids (table 4 and **Appendix 2**). Alkaloids are a large group of nitrogen-containing secondary metabolites of plant, microbial or animal origin (Hamid *et al.*, 2010). The term originally implied pharmacologically active bases of plant origin, but the definition has subsequently been broadened to include majority of nitrogen containing natural products with the exception of simple aminoacids, proteins and nitrogen-containing substances of polyketide origin such as the aminoglycoside antibiotics. They are bitter and some are very toxic and are normally classified according to their pharmacological properties e.g. analgesic, stimulant or anti-malarial alkaloids, or according to their sources e.g opium, vinca and cinchona alkaloids (Kashani *et al.*, 2012). Alkaloids from the genus *Rauwolfia* can be classified into a number of skeletal classes. The main alkaloid types identified from the stem bark of *R. caffra* includes; ajmaline (**8**) which contains both 5, 16 and 7, 17 bonds. Almost all the bases in this group contain the same skeleton, however, perakine (**93**) and raucaffrinoline (**94**) afford a rare structural variation in which the 21, N bond has been replaced by a 19, N bond; heteroyohimbines (**29, 31, 117-122**); E-seco indole (**69-73**); indolenine (**93-94**) and indole (**59-63, 96**).

## CHAPTER THREE

### METHODOLOGY

#### 3.1 Collection of plant materials

The leaves of *M. oleifera* and *R. caffra*, and stem bark of *R. caffra* were collected from Kuria County in Western region of Kenya, approximately 200 Km from Kisumu city in March 2012. The plant materials were identified by a botanist; Mr. Bethwel Owuor and deposited at the University of Nairobi herbarium, School of Biological Sciences, College of Biological and Physical Sciences.

#### 3.2 Extraction of plant materials

##### 3.2.1 Extraction from the leaves of *M. oleifera*

The fresh healthy leaves of *M. oleifera* were washed, air dried in the tissue section of the laboratory at room temperature for one week and ground into fine powder. The powder (200 g) was weighed and serially extracted in the following order of increasing polarities; 100 % *n*-hexane (C<sub>6</sub>H<sub>12</sub>); CH<sub>2</sub>Cl<sub>2</sub>:C<sub>6</sub>H<sub>12</sub> (1:1); 100 % CH<sub>2</sub>Cl<sub>2</sub>; MeOH: CH<sub>2</sub>Cl<sub>2</sub> (1:1) and 100 % MeOH for 24 hours with frequent stirring. The extract was filtered using cotton wool to remove particulate matter and the solvent removed *in vacuo* using a rotary evaporator to obtain crude extracts.

##### 3.2.2 Extraction from the stem bark and leaves of *R. caffra*

The stem bark and leaves of *R. caffra* were extracted as described under the section 3.2.1 (Extraction from the leaves of *M. oleifera*).

##### 3.2.2.1 Fractionation of *R. caffra* stem bark extract

The MeOH: CH<sub>2</sub>Cl<sub>2</sub> (1:1) extract (15 g) of the stem bark of *R. caffra* was adsorbed onto 15 g of silica gel (70-230 mesh) and then loaded onto 150 g silica gel column in 50 % CH<sub>2</sub>Cl<sub>2</sub>: *n*-C<sub>6</sub>H<sub>12</sub>. The column was eluted with the following solvent systems in increasing polarities; CH<sub>2</sub>Cl<sub>2</sub>: *n*-C<sub>6</sub>H<sub>12</sub>; MeOH: CH<sub>2</sub>Cl<sub>2</sub> yielding 120 fractions (50 ml each). Fractions with similar TLC profile were combined and concentrated to dryness on a rotary evaporator giving a total of 16 fractions coded as F<sub>A</sub> - F<sub>P</sub>.

### 3.3 Phytochemical analysis of the plant materials

The different classes of phytochemicals present in the extracts of the two plants were detected using standard procedures and the phytochemicals analyzed were; flavonoids, coumarins, phenols, alkaloids, steroids, saponin, terpenoids and cardiac glycosides.

**3.3.1 Detection of flavonoids:** MeOH extract of *M. oleifera* leaves, *R. caffra* leaf extracts (MeOH: CH<sub>2</sub>Cl<sub>2</sub> 1:1), *R. caffra* stem bark extract (MeOH: CH<sub>2</sub>Cl<sub>2</sub> 1:1) and *R. caffra* stem bark fractions were tested for the presence of flavonoids using the following tests;

**3.3.1.1 Ammonia test:** 0.5 g of the crude extract was dissolved in minimum quantities (5 ml) of the solvent (CH<sub>2</sub>Cl<sub>2</sub>) and then spotted on a TLC plate. The spot on the plate was fumigated with ammonia and appearance of a yellow spot or yellow green fluorescence under ultraviolet light (UV) was interpreted to show the presence of flavonoids (Cai *et al.*, 2011).

**3.3.1.2 Aluminum chloride (AlCl<sub>3</sub>) test:** 0.5 g of the crude extract was dissolved in minimum amounts of the solvent (5 ml CH<sub>2</sub>Cl<sub>2</sub>) and spotted on a filter paper which was then dried and sprayed with AlCl<sub>3</sub> reagent. The appearance of yellow spots or yellow green fluorescence under UV was interpreted to indicate the presence of flavonoids (Cai *et al.*, 2011).

**3.3.1.3 Hydrochloric acid-Mg reaction:** Approximately 0.5 g of magnesium turnings were added into a test tube with 3 ml test samples, and a few drops of concentrated HCl added. Change in color to red indicated the presence of flavonoids (Cai *et al.*, 2011).

**3.3.2 Detection of coumarins and lactones:** For identification of coumarins and lactones the opened loop-closed loop response was used. Two drops of 1 % sodium hydroxide solution was added to a test tube containing 5 ml solution of the extract. This mixture was incubated for 3 min in boiling water, after which 4 drops of 2 % HCl were added. Turbidity implied the presence of either coumarins or lactones (Cai *et al.*, 2011).

### 3.3.3 Detection of phenolics and tannins

The extracts and fractions were tested for the presence of phenolic compounds using the following tests;

**3.3.3.1 Ferric chloride test:** The extract (50 mg) was dissolved in 5 ml of distilled water, few drops of 5 % ferric chloride solution was added to the test tube containing 5 ml of the extract. A dark green or bluish green color indicated the presence of phenolic compounds (Cai *et al.*, 2011).

**3.3.3.2 Vanillin-HCl reaction:** 0.5 g of crude extract was dissolved in 5 ml CH<sub>2</sub>Cl<sub>2</sub> and a drop of the extracts was placed on a filter paper, dried and sprayed with vanillin HCl reagent. Appearance of varying degrees of red color indicated the presence of phenols (Cai *et al.*, 2011).

### **3.3.4 Detection of terpenoids**

To detect terpenoids the following tests were performed;

**3.3.4.1 Acetic anhydride-sulphuric acid (H<sub>2</sub>SO<sub>4</sub>) test:** 2 ml of the extract was added to 2 ml of a mixture of acetic anhydride and concentrated H<sub>2</sub>SO<sub>4</sub>. Formation of green rings indicated the presence of terpenoids (Savithamma *et al.*, 2011).

**3.3.4.2 *p*-anisaldehyde test:** 0.5 g of the crude extract and fractions was dissolved in the solvent (CH<sub>2</sub>Cl<sub>2</sub>) and spotted on TLC plate. The plate was developed using the most appropriate solvent (3 % MeOH/CH<sub>2</sub>Cl<sub>2</sub>) as mobile phase and dried. Plates were then sprayed with *p*-anisaldehyde reagent and dried at 105 °C for a few minutes. The formation of colored bands on the plate indicated the presence of terpenoids.

### **3.3.5 Detection of saponin**

The following classification tests were performed to detect the presence of saponins.

**3.3.5.1 Vanilin-H<sub>2</sub>SO<sub>4</sub> tests:** 0.5 g of the crude extract was dissolved minimum amounts of the dissolving solvent (5 ml of CH<sub>2</sub>Cl<sub>2</sub>) and spotted on TLC plate. The plate was developed in 3 % MeOH/CH<sub>2</sub>Cl<sub>2</sub> as mobile phase and dried. Plates were then sprayed with 1 % vanilin and then 5 % H<sub>2</sub>SO<sub>4</sub> reagent and dried at 105 °C for a few minutes. The appearance of a dark bluish spot indicated the presence of saponins (Sindhu, 2011).

**3.3.5.2 Froth test:** 0.5 g of the extract was dissolved in 10 ml of distilled water in a test tube and shaken vigorously for 30 seconds, and then allowed to stand for 45 min; the appearance of persistent frothing indicated the presence of saponins (Savithramma *et al.*, 2011).

### **3.3.6 Detection of pyosterols**

Salkowskis test was used to classify the compounds. 10 ml of chloroform (CH<sub>3</sub>Cl) was added into a test tube containing 1 ml of test samples, equal volume of concentrated H<sub>2</sub>SO<sub>4</sub> was added at the sides of a test tube. Appearance of yellowish colour with green fluorescence in the H<sub>2</sub>SO<sub>4</sub> layer indicated the presence of phytosterols (Savithramma *et al.*, 2011).

### **3.3.7 Detection of alkaloids**

Wagners test was used. To 3 ml of the solution of the extract and fractions, few drops of Wagner's reagent were added by the side of the test tube. Formation of a reddish brown precipitate confirmed the test as positive (Tiwari *et al.*, 2011).

### **3.3.8 Detection of cardiac glycosides**

The Keller-Killani test was used. 5 ml of each extract was treated with 2 ml of glacial acetic acid containing one drop of ferric chloride solution. This was underlayered with 1 ml of concentrated sulphuric acid. A greenish ring in the upper layer and a brown ring at the interface indicated the presence of cardiac glycosides (Cai *et al.*, 2011).

## **3.4 Biological Activity Studies**

### **3.4.1 Radical Scavenging Test**

#### **3.4.1.1 DPPH radical scavenging test using TLC**

The crude extracts obtained from the leaves of *M. oleifera*, leaves and stem bark of *R. caffra* were subjected to preliminary antioxidant activity on TLC plate and developed using different solvent system (*n*-C<sub>6</sub>H<sub>12</sub>, CH<sub>2</sub>Cl<sub>2</sub> and MeOH) to obtain well resolved spots on the plate. The TLC plates were air dried and compounds detected under UV lamp at 254 nm. The plates were sprayed with DPPH reagent (prepared by dissolving 12 mg of DPPH reagent in 50 ml of analytical grade MeOH) to detect the presence of antioxidant compounds in the extract. The colour discharge of DPPH (purple) to white at the spots was an indication of radical scavenging properties of the crude extract and fractions (Wang *et al.*, 2012).

### 3.4.1.2 DPPH radical scavenging test using spectrophotometry

Following preliminary antioxidant assay, the leaf extract (MeOH) of *M. oleifera*, leaf extract of *R. caffra* (CH<sub>2</sub>Cl<sub>2</sub>: MeOH; 1:1 and MeOH only) and the extract of the stem bark of *R. caffra* (CH<sub>2</sub>Cl<sub>2</sub>:MeOH; 1:1 and MeOH only) were selected for DPPH radical scavenging activity assay as described by Erasto *et al.*, (2011). RSA assay was also performed on the fractions obtained from the stem bark of *R. caffra*. A total of 200 µg of each extract was weighed, dissolved in double distilled methanol and serially diluted to the desired concentrations (3.13 µg/ml-200 µg/ml). 0.5 ml was added to 3 ml of 0.1 mM DPPH that had been dissolved in methanol and incubated for 30 min at room temperature. Quercetin (at a concentration of 100 µg/ml) a commercially available standard was used as a control and the absorbance was measured at 517 nm using a thermo UV spectrophotometer. The decrease in optical density (OD) indicated the presence of RSA and the percent RSA was calculated as follows:

$$\text{RSA (\%)} = ((A_{\text{blank}} - A_{\text{sample}}) / A_{\text{blank}}) * 100$$

Where  $A_{\text{blank}}$  refers to the OD of the control while  $A_{\text{sample}}$  refers to the OD of the test sample (Erasto *et al.*, 2011).

## 3.5 Anti-proliferation assay

### 3.5.1 Cell lines

Rhabdomyosarcoma (RD) cell lines (from human muscles) passage number 2 and hepatocellular carcinoma (Hep-G2) cell lines (from human liver) passage number 3 were obtained from KEMRI while Vero cell lines passage number 2 was obtained from the department of Veterinary Services, Kenya. The Vero cell lines were used as control cells for comparison with RD and Hep-G2 model (Machana *et al.*, 2012).

### 3.5.2 Cell Culture preparation and maintenance

The cells were grown in medium containing Dubelcos Minimum Essential Medium (DMEM) from Sigma-Aldrich, 10 % (v/v) Fetal Bovine Serum (FBS) from Gibco, 2 mM L-glutamine and 1 % penicillin/streptomycin (penstrep) from Kobian. The cells were maintained in a humidified incubator at 37 °C, 5 % CO<sub>2</sub> and those that had reached cellular confluence were trypsinized with 0.25 % trypsin, 2 mM EDTA and re-suspended in the medium.

### 3.5.3 Anti-proliferative assay

Cytotoxicity assay was carried out according to the method of Rakad and Jumaily (2010). The extracts were dissolved in Dimethyl Sulfoxide (DMSO) and diluted with DMEM medium to give concentration ranging from 31.25-500  $\mu\text{g/ml}$ . The cells were plated at a density of  $1 \times 10^4$  cells/well in a 96-well plate, incubated for 24 hrs at 37 °C and 5 %  $\text{CO}_2$ , after which they were treated with crude extracts (leaf extract (MeOH)) of *M. oleifera* and stem bark extract of *R. caffra* (MeOH:  $\text{CH}_2\text{Cl}_2$ ; 1:1) at various concentrations and incubated for 24, 48 and 72 hrs. Four replicate wells were prepared for each individual concentration and negative control cultures contained DMEM only. 50 $\mu\text{l}$  of crystal violet stain was added to the wells and the plates were incubated in a  $\text{CO}_2$  incubator for 30 min at 37 °C. The cells were washed gently with distilled water three times and air dried. The optical density (OD) was recorded on ELISA reader at 450 nm. The inhibitory rate of cell growth was calculated as follows;

$$\text{Inhibition (\%)} = ((\text{OD of control wells} - \text{OD of test wells}) / \text{OD of control wells}) * 100$$

The  $\text{IC}_{50}$  value was calculated using SPSS version 16 and the significant difference between control and sample means was assessed using student *t* test; *p* values  $\leq 0.05$  was considered to be statistically significant.

## CHAPTER FOUR

### RESULTS

#### 4.1 Classes of compounds identified from extracts of *M. oleifera*

Phytochemical screening of the extract of the leaves of *M. oleifera* obtained by using methanol revealed the presence of the following classes of compounds; flavonoids, coumarins, steroids, cardiac glycosides, alkaloids, terpenoids, saponin, phenols and tannins. Phenolics, steroids and cardiac glycosides were the most abundant classes of compounds (Table 5). To ensure reproducibility of the results, more than one classification test was carried out for the same class of compounds. These tests showed consistency for each class of compound with insignificant differences in abundance in some cases.

**Table 5:** Classes of phytochemicals detected in the MeOH extract of the leaves of *M. oleifera*

Class of Compounds	Classification Test	Abundance <i>M. oleifera</i> leaves
<b>Alkaloids</b>	Wagnes test	+
<b>Terpenoids</b>	<i>p</i> -anisaldehyde test	+

### 4.3 Biological activity

#### 4.3.1 Antioxidant activity

##### 4.3.1.1 Antioxidant activity of the extracts of *R. caffra* leaves and stem bark and leaves of *M. oleifera*

Preliminary RSA using 1, 1-diphenyl-2-picrylhydrazyl (DPPH) free radical as a spray reagent on TLC plates; of the leaves and stem bark extracts of *R. caffra* (50 % MeOH/CH<sub>2</sub>Cl<sub>2</sub>), the leaves and stem bark extracts of *R. caffra* (100 % MeOH) and the MeOH extract of the leaves of *M. oleifera*; indicated the presence of compounds with RSA. Quantitative antioxidant activity assay revealed the extract of the stem bark of *R. caffra* obtained using 50 % MeOH/CH<sub>2</sub>Cl<sub>2</sub> to have the highest RSA of 96.03 % at 0.2 mg/ml while the methanol extract of *M. oleifera* showed the least RSA of 83.84 % at 0.2 mg/ml (Table 5). It is important to note that even at lower concentrations (0.05 mg/ml) the RSA of *R. caffra* (50% MeOH in CH<sub>2</sub>Cl<sub>2</sub>) was 91.57 % almost as high as that observed for 0.2 mg/ml (Table 7).

**Table 7:** % RSA of the extracts of the leaves (MeOH; MeOH: CH<sub>2</sub>Cl<sub>2</sub>, 1:1), stem bark (MeOH; MeOH: CH<sub>2</sub>Cl<sub>2</sub>, 1:1) of *R. caffra* and leaves of *M. oleifera* (MeOH)

Conc. of extract µg/ml	% RSA					
	<i>R. caffra</i>				<i>M. oleifera</i>	
	Leaves		Stem bark		Leaves	
Neat MeOH	50 % MeOH:CH <sub>2</sub> Cl <sub>2</sub>	Neat MeOH	50 % MeOH:CH <sub>2</sub> Cl <sub>2</sub>	Neat MeOH	Querc	
003.13	00.25	56.42	06.21	46.00	33.00	42.18
006.25	01.03	58.44	09.61	46.94	33.00	69.31
012.50	01.33	74.88	10.48	72.39	33.00	89.71
025.00	02.23	77.51	16.75	78.79	37.78	92.89
050.00	14.16	85.50	18.90	91.57	60.37	95.29
100.00	46.32	86.42	52.12	93.15	61.00	96.39
200.00	86.11	88.44	84.64	96.03	83.84	-

% RSA are the means of triplicate measurement (n = 3); the concentration of the extract was double that of the standard compound, quercetin

#### **4.3.1.2 The relationship between Radical Scavenging Activity (RSA) and the composition of fractions of the stem bark extract (50 % MeOH/CH<sub>2</sub>Cl<sub>2</sub>) of *R. caffra***

The 50 % MeOH/CH<sub>2</sub>Cl<sub>2</sub> extract of the stem bark of *R. caffra* and the MeOH extract of the leaves of *M. oleifera* exhibited % RSA of 96.03 and 83.84 respectively at the initial tested concentration of 0.2 mg/ml (Table 7). These extracts were subjected to serial dilution to yield minimum concentrations of 0.003 mg/ml which were active with % RSA of 46.00 for *R. caffra* stem bark and 33.00 for *M. oleifera* extracts (Table 7). Having shown activity even at lower concentrations, the extract of the stem bark of *R. caffra* was fractionated by column chromatography. The fractions (sixteen) were analyzed for their RSA using DPPH reagent and the composition of classes of compounds present was detected using multiple functional group tests.

Modest blend effect was observed in the following family of compounds; alkaloids, steroids, cardiac glycosides, saponins and terpenoids had a % RSA of 58.99±1.9 at 0.2 mg/ml. The absence of saponins led to reduction of % RSA to 38.18±3.6 at the same concentration (Table 8). The highest activity (82.39±1.4 %) was observed when two classes of compounds (alkaloids and saponins) were not detected; as exhibited by the fraction eluted with 5-7 % MeOH/CH<sub>2</sub>Cl<sub>2</sub> consisting of only steroids, cardiac glycosides and terpenoids (Table 8).

**Table 8:** Relationship between the phytochemistry of the fractions of the extract (50 % MeOH/CH<sub>2</sub>Cl<sub>2</sub>) from the stem bark of *R. caffra* and RSA

Fraction	Alkaloids	Steroids	Cardiac glycosides	Saponins	Terpenoids	% RSA
F <sub>A</sub> 5-10% CH <sub>2</sub> Cl <sub>2</sub> / <i>n</i> -C <sub>6</sub> H <sub>12</sub>	+	+	+	+	-	41.82±3.3

### 4.3.2 Anti-proliferative activity

#### 4.3.2.1 Anti-proliferation activity of the methanol extract of *M. oleifera* leaves

Anti-proliferative activity of *M. oleifera* leaf extracts (MeOH) was carried out on Hep-G2, RD and Vero cell lines and monitored over a period of 72 hrs at different concentration (Table 9). *M. oleifera* leaf extracts (MeOH) significantly inhibited the growth of Hep-G2 and RD cell lines ( $p < 0.05$ ), and the optimum quantity required to suppress the growth of 50 % of cancer cell lines (IC<sub>50</sub>) is presented in table 10. Further analysis showed *M. oleifera* leaf extracts (MeOH) to inhibit the growth of all the cell lines in a dose and time dependent manner and the highest inhibition was recorded after every 72 hrs on all the cell lines (Table 9); the proliferation of Hep-G2 and RD cell lines was also significantly affected (Table 10).

**Table 9:** Percentage inhibition of Hep-G2, RD and VERO cell lines by methanol extract of *M. oleifera* leaves after 24, 48 and 72 hrs of exposure

Concentration (µg/ml)	Inhibition %

#### 4.3.3.2 Anti-proliferation activity on cancer cell lines by *R. caffra* stem bark extracts

(MeOH: CH<sub>2</sub>Cl<sub>2</sub>; 1:1)

The anti-proliferative activity of *R. caffra* stem bark extracts (MeOH: CH<sub>2</sub>Cl<sub>2</sub>; 1:1) was carried out on Hep-G2, RD and Vero cell lines. The bioactivity of crude extract from the stem bark (MeOH: CH<sub>2</sub>Cl<sub>2</sub>; 1:1) of *R. caffra* on Hep-G2 and RD cell lines as well as the optimum quantity required to suppress the growth of 50 % of the cells (IC<sub>50</sub>) is presented in tables 11 and 12. The anti-proliferative activity of *R. caffra* stem bark extracts (MeOH: CH<sub>2</sub>Cl<sub>2</sub>; 1:1) against the three cell lines was not statistically significant ( $p > 0.05$ ). The extracts inhibited the growth of all the cell lines in a dose dependent manner and the highest inhibition was recorded after 72 hrs (Table 11).

**Table 11:** Percentage inhibition of the growth of Hep-G2, RD and Vero cell lines by *R. caffra* stem bark extracts (MeOH: CH<sub>2</sub>Cl<sub>2</sub>; 1:1) after 24, 48, and 72 hrs of exposure

Concentration (µg/ml)	Inhibition %

Empty cells represent negative values.

**Table 12:** IC<sub>50</sub> values for Hep-G2, RD and VERO cell lines after 72 hrs exposure to *R. caffra* crude stem bark extract (MeOH: CH<sub>2</sub>Cl<sub>2</sub>; 1:1)

	IC <sub>50</sub> (mg/ml)		P value
Hep-G2	0.89	<b>Hep-G2 vs VERO</b>	0.059
RD	0.19	<b>RD vs VERO</b>	0.081
VERO	0.60		-

IC<sub>50</sub> Half maximal inhibitory concentration

## CHAPTER FIVE

### DISCUSSION

#### 5.1 Overview

This study evaluated the efficacy of phytochemicals present in two plants (*R. caffra* and *M. oleifera*) used in traditional health care to manage cancer and related illnesses. A clear disparity was observed in the phytochemical composition of the extracts of the two medicinal plants although they are used to manage the same ailment. The 50 % MeOH/CH<sub>2</sub>Cl<sub>2</sub> extract of stem bark of quinine tree displayed substantial antioxidant activity as compared to the leaves of drumstick extracted with methanol, which exhibited better anti-proliferative activity against Hep-G2 and RD cell lines. These results imply that the composition of the extract in terms of the class of compounds present determines the activity of the extracts, as some compounds antagonize while others boost each others activities.

#### 5.2 Classes of compounds identified from extract of *M. oleifera*

Phytochemical screening of medicinal plants is key to the identification of new sources of therapeutically and industrially important compounds (Savithramma *et al.*, 2011). Phytochemical analysis was performed on crude extracts of *M. oleifera* leaves (MeOH) and the extracts were found to be rich in phenolic compounds but to contain low levels of alkaloids (Table 5). This is consistent with Rajula and Ujwala, (2010) findings which showed *M. oleifera* to contain low level of alkaloids. The class of phytochemicals present in a plant may assist in predicting its biological activities; for instance, flavonoids and tannins are strong antioxidant agents due to their ability to scavenge free radicals (Dai and Mumper, 2010; Si Heung Sung, 2012; Zhang *et al.*, 2010) while coumarins are anti-mutagenic agent (Lacy and O’Kennedy, 2004; Mirunalini and Krishnaveni, 2011). Thus, *M. oleifera* is generally expected to have antioxidant and antitumor properties.

The identification of cardiac glycosides (Table 5) in the current study is consistent with previous studies (Rajula and Ujwala, 2010). Cardiac glycosides are molecules used in treatment of heart diseases (Kashani *et al.*, 2012) hence, *M. oleifera* extracts may be used to manage heart diseases as is currently practiced by many communities across the world. These results therefore reaffirm the value of indigenous knowledge in identification of plants for pharmaceutical use.

### **5.3 Classes of compounds identified from extract of *R. caffra***

The stem bark extract (MeOH: CH<sub>2</sub>Cl<sub>2</sub>; 1:1) of quinine tree was found to be rich in alkaloids (Table 6). The detection of alkaloids in the stem bark extract (MeOH: CH<sub>2</sub>Cl<sub>2</sub>; 1:1) of *R. caffra* further reinforces the presence of alkaloid in this species as already outlined by other independent studies (Erasto *et al.*, 2011; Nasser and Court 1984). This class of compounds have wide pharmacological effects and has been used extensively as drugs in medical field; examples of alkaloids of pharmaceutical importance from *R. caffra* include; ajmalicine (**29**), reserpinine (**126**) and reserpine (**169**) which are used as antihypertensive and anti-inflammatory agents (Kashani *et al.*, 2012; Vakil, 1955). Saponins; the other group of phytochemicals detected in *R. caffra*, are compounds with a wide array of biological effects. They have been shown to have antimicrobial, antiviral, antioxidant and cytotoxic properties, however, this compounds are known to interfere with the digestion of protein and uptake of vitamins and minerals (Francis *et al.*, 2007). Hence, they are mainly used as detergents and surface active agents in industries (Savithramma *et al.*, 2011).

One unanticipated finding was the absence of phenolic compounds in the extracts of *R. caffra*. The leaves of this plant contain wax which is rich in phenolic compounds. Surprisingly, these were not detected even by using multiple tests. It is possible that most of the polyphenols were lost in the solvent system (hexane and DCM) before the extracts were subjected to subsequent analysis on methanol.

### **5.4 Biological activities**

#### **5.4.1 Radical scavenging activity of extract from *M. oleifera***

In the current study, methanol was used as a negative control in all the tests and it had a 0.00% radical scavenging capacity. The commercially available quercetin; used as a positive control had a RSA of 96.39 % at 0.1 mg/ml, implying that the method used was reliable for determining antioxidant activity. The methanol extract of the leaves of *M. oleifera* had a low RSA of 61.00 % at 0.1 mg/ml (Table 8). This low antioxidant activity exhibited by *M. oleifera* extracts in the current study was indeed unanticipated since phytochemical analysis revealed the presence of phenols which are known to be rich antioxidants (Mirunalini and Krishnaveni, 2011; Si Heung Sung, 2012). The low antioxidant activity of *M. oleifera* extracts can be attributed to the

reduction in the efficacy of antioxidant molecules in the plant post harvesting; the long duration between sample collection and analysis could have influenced the molecules capacity to scavenge the free radicals. Moreover, other confounding factors such as; geographical distribution, soil composition and the age of the plants may have influenced the antioxidant activity of the plant (Mokale *et al.*, 2011). Indeed, a study by Iqbal and Bhanger, (2006) established that seasons and geographical locations may influence the concentrations of antioxidants in *M. oleifera* leaf extract.

#### **5.4.2 Radical scavenging activities of extract from *R. caffra***

Extracts from the stem bark of *R. caffra* revealed a strong dose-dependent RSA against DPPH (Table 7) which is consistent with previous findings (Erasto *et al.*, 2011; Gbonjubola, 2010). The % RSA of *R. caffra* stem bark extracts was 93.15 % at 0.1 mg/ml while that of the standard quercetin was 96.39 % at 0.1 mg/ml, suggesting *R. caffra* stem bark extract to be a competitively strong antioxidant. The results show that *R. caffra* was tested at double the concentration of quercetin and from the table the activity of the standard is higher but comparable to that of the extract of *R. caffra*.

Further analysis performed on the fractions obtained from the stem bark of *R. caffra* showed activity variations in RSA depending on the phytochemical composition. For instance, the alkaloids exhibited improved RSA in the absence of other classes of phytochemicals (Table 8). RSA was consistently lower in fractions exhibiting the presence of alkaloids and other phytochemicals concurrently pointing to a possibility of these compounds having antagonistic effect with alkaloids. For instance, alkaloids and saponins appeared to have antagonistic interaction, at least with regards to RSA. This potentially lowers their activity as antioxidants, and possibly the potency of extracts containing both compounds. Although the antagonistic interaction of biomolecules in drumstick was not determined, it is probable that the low RSA of the MeOH extract of *M. oleifera* is due to antagonistic effect of the classes of compounds in the extract, rendering the whole extract less effective with respect to antioxidant activity.

### 5.4.3 Anti-proliferative activity

#### 5.4.3.1 Anti-proliferation activity of *M. oleifera* leaves extracts

The MeOH extract of *M. oleifera* demonstrated prominent anti-proliferative activity on both Hep-G2 and RD cell lines. This findings are consistent with those of Khalafalla *et al.*, (2010) who found hot water extracts of *M. oleifera* to have significant cytotoxic activity against Hep-G2 cell lines. The authors attributed the strong anticancer activity of *M. oleifera* extracts to the presence of phenolic compounds (Khalafalla *et al.*, 2010), it is likely that the same class of compounds were responsible for the anti-proliferative activity observed in the current study. Another important finding is the low cytotoxicity of MeOH extract of *M. oleifera* leaves against Vero cells. After 72 hrs of exposure of the cells to high concentrations of the extract (500 µg/ml), the cytotoxic effect was found to be less than 50 % (Table 9), an indication that the extract is less toxic to normal cells. Previous studies have found *M. oleifera* to be potentially non-toxic (Kasolo *et al.*, 2011) validating its traditional use as a vegetable (Fahey, 2005), water disinfectant (Lantagne *et al.*, 2008) and as a medicinal herb (Fahey, 2005).

#### 5.4.3.2 Anti-proliferation activity of *R. caffra* stem bark extracts

The MeOH: CH<sub>2</sub>Cl<sub>2</sub> (1:1) extracts of *R. caffra* stem bark inhibited the growth of all the cell lines in a dose dependent manner and as anticipated, the highest concentration (500 µg/ml) had the highest anti-proliferative effect (Table 11). An important finding in the current study, was the fact that the extracts greatly inhibited the growth of control cell lines (Vero cells); there was no significance difference in the anti-proliferative activity of *R. caffra* stem bark extract (MeOH: CH<sub>2</sub>Cl<sub>2</sub>; 1:1) on Hep-G2 cells and normal Vero cells ( $p > 0.05$ ) cells, implying that the extracts could be toxic to normal cells (Table 12). The cytotoxicity observed in the MeOH: CH<sub>2</sub>Cl<sub>2</sub> (1:1) extract of *R. caffra* could be attributed to the presence of alkaloids such as akuamicine (**33**) (Nasser and Court, 1984), dihydroperaksine (**59**) and macrocaffine (**26**) (Nasser and Court, 1983) detected in earlier studies. Further, a comparative analysis revealed RD cell lines to be more sensitive than Hep-G2 when exposed to extracts of the two plants, however this was more prominent in the case of *R. caffra* extracts where Hep-G2 cell lines gave inconsistent results due to the resilience nature of the cell line, indeed a study by Mahavorasirikul, *et al.*, (2010) found Hep-G2 cell lines to be resistant to most of the plant extracts tested.

## 5.5 General discussion

A comparison of the phytochemical component of the two plants revealed the leaves of *M. oleifera* (MeOH) to be rich in phenolic compounds while *R. caffra* stem bark extracts (MeOH: CH<sub>2</sub>Cl<sub>2</sub>; 1:1) was found to be rich in terpenoids and alkaloids ( Tables 5 and 6). The variation in phytochemical composition may be responsible for the disparity in the antioxidant and anti-proliferative activity of the two plants; the MeOH extract of the leaves of *M. oleifera* was found to have better anti-proliferative activity than *R. caffra* stem bark extract (MeOH: CH<sub>2</sub>Cl<sub>2</sub>; 1:1). Apart from its anti-proliferative properties, *M. oleifera* leaf extracts also have hepato-protective (Das *et al.*, 2012; Verma *et al.*, 2012), antioxidant (Das *et al.*, 2012; Paliwal, *et al.*, 2011; Verma *et al.*, 2012) and antibacterial activities (Peixoto *et al.*, 2011). The stem bark of *R. caffra* (MeOH: CH<sub>2</sub>Cl<sub>2</sub>; 1:1) on the other hand exhibited the highest antioxidant activity making it a good source of natural antioxidants. However, these extracts were also found to be toxic to vero cells, the problem of cytotoxicity can be resolved by adopting modern biotechnology during extraction to minimize toxicity and to optimize the bioactivity of compounds from *R. caffra*.

Phytochemicals in the stem bark extract (MeOH: CH<sub>2</sub>Cl<sub>2</sub>; 1:1) of *R. caffra* were observed to have synergistic and antagonistic activity. For instance, saponins and alkaloids showed possibilities of having a negative blend effect on steroids, cardiac glycosides and terpenoids. A combination of saponins and alkaloids antagonized each other resulting to a substantial reduction in activity; the fraction with alkaloids had a RSA of 62 % and inclusion of saponin reduced activity to 15 %. This findings support previous suggestions that synergistic and antagonistic activity in medicinal plants may lower the concentration of bioactive ingredient to suboptimal levels or increase their concentrations to toxic levels resulting in severe side effects (Doughari *et al.*, 2009). In traditional medicine as practiced by the Abakuria community of Kenya, *R. caffra* is normally administered as a concoction: It's possible that the activity of the toxic molecules is antagonized by other compounds that are incorporated in the herbal concoction thus lowering their toxicity.

## CHAPTER SIX

### 6.1 Conclusion

This study has shown that the leaves of *R. caffra* and the stem bark of *M. oleifera* indeed have phytochemicals of known health benefits, for instance;

- The extracts of the leaves of *M. oleifera* (MeOH) were found to be rich in cardiac glycosides and phenolic compounds such as flavonoids, coumarins and tannins.
- The extracts of the stem bark of *R. caffra* (MeOH: CH<sub>2</sub>C<sub>12</sub>; 1:1) were found to contain phytochemicals such as cardiac glycosides, alkaloids, saponins, steroids and terpenoids.

With reference to bioactivity the major findings were;

- The bioactivity of the phytochemicals in the stem bark of *R. caffra* crude extract fractions was found to be suboptimal in certain instances due to a possibility of antagonistic effects between alkaloids and saponins.
- The extracts of the stem bark (MeOH: CH<sub>2</sub>C<sub>12</sub>; 1:1) of *R. caffra* was toxic to vero cells (representative of non cancerous mammalian cells), the same extract however, was found to have high RSA an indication that it may be effective in managing diseases related to oxidative stress if administered in the appropriate doses.
- Extracts from the leaves of *M. oleifera* (MeOH) on the other hand exhibited significant anti-proliferative activity against RD and Hep-G2 cell lines an indication that it might be a suitable source of chemotherapeutic molecules.

## 6.2 Recommendation

- To determine the antioxidant and anti-proliferative activity of drumstick and quinine tree, crude extracts were used; such extracts contain a mixture of compounds that may have synergistic and antagonistic activity. These effects can be overcome by using pure compounds isolated using preparative High Performance Thin Layer Chromatography (HPTLC) and High Performance Liquid Chromatography (HPLC), and their structure resolved using high resolution mass spectrometry (HRMS) and Nuclear Magnetic Resonance (NMR).
- In view of the revelation that antagonistic interactions influence bioactivity (perhaps explaining the lack of correlation between anticancer and antioxidant activity), testing pure compounds isolated from the two plants can shed insights into skeletal structure-activity relationship.
- This study utilized only two cell lines (RD and Hep-G2) though cell lines respond differently to the same treatment. This may have limited the true value of these plants as potential for cancer treatment. Pure isolates from the two plants should be tested against other types of cancers such as prostate or breast cancer.
- In the current study the anti-proliferative activity was performed on cell lines. However, bioactivity of the extracts may vary between *in-vivo* and *in-vitro* models. It would be valuable to test these extracts and constituent compounds *in-vivo* using a model such as mice.
