## Abstract.

Yo attenpt to elaseify the dialecta of Sonthers Mt. Xenya on the basis of historical sound changen. ©p to mev, all the dialects of theaeregions have generally boen regarded as varieties of the Kikuym langage. There hee not beon any attempt to find out the difforemees that exist between these dialeots. The only work that Inknov of is that of Prof. Mohlig (1974) which has claselfied the dialects of North Eastern Mt. Konja.

Prof. Mohlig's vork does not deal with the dialecte of Sourthern Mt. Kenya. The only dialects of this region that he has discussed are Ki-Enbu and Ki-Mbeere. It is true therefore to argue that there is no literature on dialectal pariation in this region.

As an introduction chapter I reveals the nonlinguistic factors that have influeaced the language situation in the area. It does not, therefore, raise the isaxes that are discussed in the other four chapters.

Chapter II deale with the morpholexical differences betwean the dialecte and the historical sound changes that have caused then. The af of the discuseion and the examples

Is to show that the dialecte differ in both lexicel and morphological structures. The changes affecting varione norphenes are discuseed within the Natural Generative Gramar (N.G.G.) and its theory of sound change.

Chapter III exenplifien cortain sound differences and analyses the changes that have caused them. The current phonological syatem of each dialect or group of dielects is traced from a common, historical, sound system. The historical sound-change rules that link the proto - and syachronic stages are discussed and forwalised. Where possible, the diachronic seouence of the changes is given.

Chapter IV discueses and exepplifiea eynchronic. phonological ralas, izcluding various ralas tingt fix differert dialect boundsines. It is the menin chaptes of the study, given ite title, and it is the lageat.

In a sumary form, chapter $\mathcal{V}$ concarna iteolf with ribe theury of sound chageg ased in this acady. The soapter discuaser the relationailp between both deap and surface and diachronic and synchronic forme. The foraer discussion poeer the eneation of whether ail the dialecta have identical underlying forme. Arguments for or against identical underyling loms are given.

In discussiag the relationship betveen diachronic and syohronic forms, the question of restructuring becomes orucial, in particular how to establict the point at when restructuring ocoured. The chapter thuc disousees restructuring and the coastraints that oer liaguintic theory needs in order to eetablish it.

Restructuring leade to rule formalation and mie

```
iaterpretation, rule conorallty and the correntmean of
its predictions are also diacussed. We rejeat any
gonerallsationg that contradiot actmal cound shnges.
```

## ACKNOUZ EDGEMENTS

This work woupd not have been posaible without the help of many devoted friends, colleagues and relatives. To then 311 I offer my heartfelt thanke.

I vould like to offer special thanks to DrE. K. Ford and $F$. Katamba whose belp, suggestions, and comments have made this study a better piece of work than it would have been othervise. I would also like to thank Profs. W. Mohlig and B. Heine for their useful comments and suggestions during the preparation for the field reserrch.

Most of all I want to thank all my informants for furaishing the information required for this study. I owe special thanks to Miss M. Wanjugu Kangi and her fanily friends, and Mr. C. Njeru Rurigi for their efforts to get we the right type of informants. Thair patience and willingness to help has been invaluable.

Lastly, I owe special thanks to all those who gave we material support during the research period. I would like to make special mention of my brother Mr. Njeru Kirira, Mr. Njogu Ndung'u, Mise Wanbui Thiong'o, Prof. T.J. Eennibusch, and the Daiversity of Nairobi who, through the Dean's Comaittee, gave me a grant for the initial research. I also owe special thanks to Dr. C.K. Ford for letting me use all the money from the grant that was given to both of us by the above comaittee. My appreciative thanke to all.

## GEAPTER ONE

People and their dialectes
1.0 Introduction.

In this chaptor wo shall linit our discuseions to the people and the dialedts of Souther Mt. Xeaya (heace s. Mt. Kenya). As an introductory chapter it vill not discuse any Iinguistic differences between the dialecta.

One of the thinge that wo shall examine in this chapter will be the problem of aingle name for the people and thedr lenguages or dialects. We shall, also examine and ovaluate the reasons behind the official classification of all these poople iato Kikuyu, Embu and Moare.

Finally we shall introduce aach daslect by reacribing its geographical location in the region. The purpose for such an introduction will be to help the reader in relating each dialect to other dialects of the region.

The conclusion will touch on preseures exerted on small dialect speakers by major dialect speakers. We shall also give figures of the distribution of epeakers of these dialects outside their home districts.

### 1.1 Aims:

a great number of the Bantu studies that have been carried out have been conflned to the classification of Bantu languages. This clasaification has been dominated
by Guthrie's vork on Comparative Bantu (1.e. 1948, 1967 1971 etc.). Guthrie's work has not gone beyond noting and stating the changes in each given language of his otudy cf. ${ }^{-P>B}$ in Enbu (Guthrie 1971).

In his work Guthrie did not discuse the diachronic order of the changes he showed. He also did not attenpt to subgroup his languages according to common sound changes of each subgroup of his regions. The first scholar, to my knowledge, to attempt to subgroup a given set of Bantu lafgaages in Hinnebusch (1973). Hinnebusch has used prefixes and sound changes as his basis for subgrouding Kenyan Coastal languages.

Hinnebusch's inputs are the sounds and prefixes reconstructed by Guthrie and Meinhof. His outputs are the present day differences and similarities between the languages of his study. Between the two he has the rules and taeir order of application.

By enploying this approach Hinnebusch is able to show any commor changes that occurred within a given set of languages. He is also able to show the languages which do not share a given change vhich is coman elsewhere. In this way be is able to subgroup the langages into enaller groups.

In the present atudy ve begin from the contemporary sounds of the dialects of S. Mt. Kenya. From the contemporary sounds we work backwards to the proto-language

```
of the region i.e. the reconstmcted forns. Prom the
reconstructed forms we work forvnrds showireg all the changea
tbat have taken place and their o:der of operatiocs.
Ressons for any orders are given for eech crdered peir.
```

Frow the above paragraph it is obvious that we have not worked $f$ rom one end like Guthrie or Hinnebusch. Gutbrie worked from top to bottom and Binaebusch vorked from botton to top. The two scholars had each his reason for his unifdirectional approach.

Our reasons for working from top to bottom and vice versa are that we are interested in reconetructing an intereediate stage betweon the present stace and Coman Bantu. We are also interested in aubgrouping a set of dialects that are closely related.

The aimo of the three studies compared above are not identical. Guthrie was interested in reconstructing Common Bantu. Hiacsbusch was interested io subgrouping set of languages by using commor Banta forme. Our aime are to reconstruct an intermediate utage between comon Bantu and the present iorms and then subgroup jialects of that substage that we reconstruct. It is true then to clain that differsat aims have necessitated different approaches.

In this study wo conpare different dialectal formes and changes in order to establish the distance between giren sets of dialects. Note, for example, that the four
eastern dialecto Ki-Enbu, Ki-Mbeere, Ki-Gichugu and Ki-Ndia, have aerged the distinction between $P$ and * $B$. The three western dialecte of Ki-Mathira, Northern and Sourthern dialects have kept this distinction intact. Such evidence as this helps us to subgroup not only languages but dialects also. The possibility of this subgrouping was denied by Guthrie (ef. 3.1).

By reconstructing an interwediate stage betweon Coman Bantu and the present forms we have avoided taking sides with either Guthrie or Meinhof. Guthrie reconstructed voiced stops i.e */b d g/while Meinhof had continuants i.e. "/B $1 \mathrm{\delta} /$. For us there is no problem of cholce (c). 3.1).

The reconstructed forms and changes ay be challeaged by those who advocated abstract ${ }^{1}$ phonology. For such scholars scme of our diachronic changes may be claimed to be in the syachronic gramuars of the speakers of these dialects. That may be true in other models of sound change but it cannot be the case in the model used in this study. In our model only the forms that do not violate the, 'Strong Naturalness Condition,' and the, 'No Ordering Condition, can be posited as synchronic forms (cf. 4.1).

In conclusion it should be pointed out that the only sounds that have been reconstructed are those whose reflexies are attested in the region. Any sound whose reflexies are not attested in the region cannot be
reconstructed as a part of the protoms. Mt. Kenya sound ntructure.

### 1.2.1 The Poople

According to 1969 census, there are 2,368,848 native apeakers of Southern Mt. Kenya dialecte. The same recorde divide these people into three ethnic groupe. These are as shown belowt-

1. (a) Kirugu
2,201,632
(b) Eabu
117.969
(c) Mbeore 49,247

Of the above, $1,763,047$ live in their howe districts (cf. map 1). This figure is broken down as follows:-
2. (a) Kikuyu $1,607,170$
(b) Embu
109,174
(c) Mbeere 46,703

According to the above ligures Eibu and Mberere are less mobile than Kikuyu. Note, for example, that 594,462 Kikuyu Iive outside their home districts i.e. outside Central Province. This is about a quarter of the Kikuyu population. For Eabu only 8,795 live outside their homedistrict. This figure is less than ten percent of Embu population. The figure for Mbeere is 2,544. These are the only people registered outside their home district. This is less than five per cent of Mbeere population.

The figures given above have important linguistic
implications. Note that if only three dialects existed Babu and Mbeere would be linguistically doainated by the aajority around them. We shall come back to linguistic dominance later.

### 1.2.2 Other Divisions

As stated above the offlcial records have recognized only three ethnic divisions. To our knowledge the three divisions are not disputed by any group. The official classification is rather arbitrary in that linguistic differences between $K i-E a b u$ and $K i-m b e e r e ~ a r e ~ l e s s ~ m a r k e d ~$ than those between Ki-Gichugu and Ki-Ndia on one side and Ki-Mathira, Northern and Southern dialects on the other (cr. chapter 2, 3, 4 nad 5). In fact there are greater differences betweez the latter groups than between the former.

Our opinion is that the dipision between Benb and Mbeere is more historical or political than linguistic. Linguistically there is no justification for this division. As will be seen in chapter III these two dialects have identical sounds. The only differences that we shall see vill be on phonological rules and in lexical itens.

This division into Mbere and Ebbutribes, as indicated in 1969 census, must have been besed on ofther historical or political resons. There may have been some disagreements in the history of these people that made then

# ask for soparate ames. An altornative to this may be some inherent insecurity of Mbeere people which makes then Pear their northern neighbours. Whatever the reasons are, for the division, they cannot be linguistic. 

The disagreements between Babu and Mbeere seen to have been 2 ess serious than the disagreements betweon the two and the Kikuyu. This is rellected by their choice to be in bestern Province other than in Central Province. Again the two agreed to be in one district i.e. Embu. It nay be of interest to note that at one stgge of our history Gichugu and Ndie vere in Sinbu district. Thg reasoas for the separation iato babu and Mirinsaga districts can only be found in a historical research.

Linguistically there would be more juetilication for a division between Gichugu-Kdia group and the vestern dialects of Mathira, Northern and the Southern dialects The linguistic differences are shown in the four following chapters of this study. Since these changes will come in later chapters we need not deal with them here.

The linguistic differences between Gichugu-Ndia group and the western group are now being used for conomic reasons. The former resent what they see as economic eacroachmentcoming in form of land acquisition. People Prom the western groups are ready to buy land at prices which the Gichugu-Ndia people rogard as being too high lor then to afford. They therefore begin to see the now buyers
as outsiders coming into their bone district. These attitudes enhance linguistic differences.

The divisions between Gichugu and Ndia have been aggravated by the political divisions of Kirinjaga district. Adoinistratively $N d i a$ is a single division while Gichugu is another. The third division of Kirinyaga is the Mwea which is of mixed people (ci, 1.3.1). The division between Gichugu and Ndia is like that of Embu and Mbeere. The two have identical solnd structure but differ in phonolocical rules.

The difference between these two groups and Embi-Mbeere group is that none of them is recogaised as a difforent ethnic group. They both belong to the Kikuyuggroup shown in 1.2. They however feel that they are different from what they regard as 'outsiders' in their district.

An example of this feeling is shovn in language use. I remember one day that ny informants and I walked throuch somebody's howe. My informant shouted greetinge to the family thus, 'Morjésà 'are you finef'. The answer frem the lady of the family was, 'Is that you, Charles, oponking like Mokabete? When I asked the reason for this my informant said that his Ki-Gichugu pronounciation should have been 'Morí́ge'.

The lady's question shows two different things. These are the pact that Gichugu people feel that they are
linguistically different and that for then everybody who speake a dialect west of Ndia is a Mokabete (a person from Kabote). For them there is no distinction betweon Northern and Sourthern or Mathira people. They sll speak Ki-Kabete. The lady did not know that the rabetg arez would haye (mory ga).

Other division that one finds in literature are Kabete, Motumi and Gaki (cf. Muriuki 1974). As is evident from our later discussions these names do not have any liaguistic significance. In the above literatures Kabete stands for Kiambu, Metumi for Murang'a and Gaki for Nyeri. None of these terns has any linguiatic backing. Even historically these nares have no role to play.

People innorthern Kiambu i.e. Gatundu denied that they bolonged to Kabete. For them Kabete is the ares near Nairobi especially between Nairobi and Limuru. For eost Murang'a people Metumi was a strange name, they had never heard of it. Nyeri people claimed that Gaki was apecific place and not a name for the whole district. For them Gaki was the area around Muthinga Market.

In conclusion ve should point out that no such divieions, as the sbove, existed before colonialism. Ihey must therefore be seen as the creation of coloaial administration. Any one trying to apply these divisions inguistically is bound to fail.
1.3.1. The Region and the Dialect:

Our region of study lies between Thuci river, to the East of Mt. Kenya, and the Aberdare Paige (Nyandarua Mountains) to the West of Mt. Kenya. Prem Mt. Kenya the region stretches southwards to the city of Nairobi (cf. map 1)

This region is in two administrative Provinces These are Central and Eastern Provinces of Kenya. The districts of Kirinyunca, Nyeri, Muranga and Kiambu are in Central Province vile Eabu district is in Eastern Province. Most of this region, lies in Central Province. -

As will be noticed from our naps of the region (cf maps 1 \& 2) Nyandarua district is left ont of the dialectal considerations. The reason for this is that this district does not have any dialect boundaries. It is a mixed area of all dialects just like Mwea division of Kirinyaga district.
1.3.2. The Dialects:

As shown in map 2 our region of study is divided into seven dialects. These are:-
3. 1. Ki - Embu
2. Ki - Mbeere
3. Ki - Gichugu
4. Ki - Nadia
5. Ki - Mathira
6. Northern dialect.
7. Southers dialect.

The reasons for this division will be discussed In chapters II, III, IV, and $V$. On linguistic ovidences the area can be divided into two regions or groups of dialects. The first group of dialects will be callod eastern dialects and the second one will be vestern diglects. Eastern dialects will be Ki-Enbu, Ki-Mbeere, Ki-Gichungu and Ki-Ndia. The remaining three dialects of Ki-Mathira, Northern and Sourthern dialects will aake the western dialects.

These two broad groups are classilied by certain sound changes and phonological rules. Note for example that the four eastern dialects have lost * ${ }^{\circ}$. $\mathrm{B}_{\mathrm{B}}$ distinction. The western dialects have reduced the paseive to? from "ra. Thece western dialects have also developed consonantal cluster reducticn (cf. 4.2.1.) Juch Pegtures an those have been used in grouping the dialectis into two abgroupe.

Since our aain concerm at this stage is to introduce each dialect wo Biall suspend dialect differencen for now. In order to be able to introduce each dialect and to locate it geographically we shall deal with each dialect separately. The order of our discussions shall be as shown in 3, above.
2.3 .3 K1 - Eabu.

This is the only dialect that Guthrie (1971) seeme to have recognised es different fron Kikuy, His exnmple, however, shows that he was talking about $\mathbb{M}$-Gichugga or Ki-Ndia and not Ki -Rabu. $\mathrm{He}_{\mathrm{e}}$ eays on page 46, 'E 52. 'Embo (Keaya). Similar to E. 52, but ${ }^{\circ} \mathrm{P}>$ B. As bhom in chapter III this change occurred in Ki-Gichunge and in Ki-Ndia but not in Ki-Bobu.

This dielect lies betweon four rivers. To the north is River Thuci, to the east River Tana, to the South River mae and to the west is River Rupingazi. This area forme Runyenjes division of Embu district (formerly Eebu divisiond.

According to the 1969 population census this dialect has 117, 969 native speakers. Out of these 109, 174 live in smbu district. The rest are scatered all over Kenya.
1.3.4. K1 - Mbeere.

Ho linguistic book has, to our knowledge, mentioned the existence of Ki - Mbeore. $\mathrm{AB}_{\mathrm{B}}$ already stated in 1.2. Mbeere are recognized as separate from both Xikuyn and Enbu. Their area lies between three rivers. These are Tane, which lies east and south of this region, Rupingazi, which lies to the west and Ena which separates Mbeere from ybu. Administratively this area is divided into two divisions of Gacoka (west) and Siakago (eastern section).

According to the ligures of 1969 population cerisus this dialect has 49, 247 antive speakers. Out of these 46,703 live in Eabu district. The rest live in other areas of Kenya.

### 2.3.5. Ki = Gichungu.

Mais dialect lies between two rivers. These are Rupingazi and Thiba. 'ino first separates Ki-Gichugu from Ki-babu ard the second separater it from Ki-Ndia. The actual houndary between Ki-Gichugu and Ki-Ndis rans along Rutui (a tributary of Thiba). To the rorth is Mr. Konya.

Recordo show that by 1969 Gichugu diviaton, wich forms the core of Ki-Gichugh speskers had 62.664. Soxe speakers of this dialect are also founi in Mwa division of Kirinyaga district. This, latter division, is an area of mixed dialects. People from all areas of central Kenya are found here.

Assuaing that a good number of Mwea residents do speak this dialect we can give it a total of 80,000 speakers at most. Note that Mwea has 58,262 people. About half of these people come from outside Kirinyaga district,

Speakers of this dielect have some ainor internal variations. This is a claí made by the people themselves. Most conspiceus variation is between Ngariana and the rest

#### Abstract

of Gichugu people. The best example of the differences between Ngariama and their neighbours is the aurfacing of the locative suffix as - $\underline{n i}$ instead of - ne that is found in all the dialects west of Ki-Embu. The differences between Ngariama (location) and the rest of Gichugu were not serious enough to warrant a separate dialect.

1.3.6. Ki - Ndia.

Ki - Ndia is spoken in Ndia division of Kirinyaga, district.
Speakers of this dialect live between rivers Thiba to the east, Tana to the south and Ragati (aitheri) to the west. On the northern side is Mt. Kenya.

In 1969 this division of Kirinyaga had 93,406 people. A small fraction of these speak Ki - Mathira. We could say that speakers of Ki-Ndia in Ndia division may be as many as 80,000 people. To this figure we should add another fraction of those who live in Mwee division. The total number of speakers of this dialect may be nearly 100,000.
1.3.7. K1 - Mathira.

This dialect is, mainly, in Mathira division of Nyeri district. It is to be found west of Ragati Hiver and between Mt. Kenya and Tana River. The native speakers of this dialect are found around Karatina town.

#### Abstract

The present day duellers of Mathira division include anre number of Northern dialect speakere. Tne number of speakers of the northern dialect in Mathira is hard to establish because there are no records showing Who speains what dialect. A conservative ention te bulu Fut the nuwber of $K i$ - Nathira spuqhere to about ? 0,000 people out of over 94,000 residents oi Mathira division.

1.3.8. Northern iialect.

This dialect is spoken in both Nyeri and Muranga. It's area lies between Chania kiver to the north, and N. Mathioya River, to the south. On the eqstern side we have Ki - Mathira and Ki - Ndia dialects and on the western side is Aberdare Range.

In population this is the second largest dialecte. It's speakers in this region are about 400,00 people. It is second to the Southern dialect.

### 1.3.9. Southern dialect.

This dialect lies between N. Mathioya River and the City of Nairobi. On the eastern side ci this dialect there are the former settled areas of Makuyu and Thika regions. This region (settled ares) is of mixed population. To the west of this dialect is tho Aberdare Iange.

Speakers of this dialect are over thrce quarters of a million. It is therefure the dominant dialect of our
region of study. Apart irom being domimant in popul tion it also used on the Voice of ie..ya (VOK) vernacular service for broadcasts to the pecfle of S. Mt. Kenya.
1.4.1. Conclusion.

In this chapter we have seen that ife of our seven dialects are spoken by minorities. None of them has more than 100,000 speakers. We have also seen that none of the minority dialects is used in broadcasting. These and other factors that we shall discuss here reveal that minority dialects are at a disadvantage.

The disadvantages we talk of include the fact that none of the five small dialects has an orthography. All the books are written in the two major dialects. Of these two the Southern's sound structure is used but the Northern's morphological structure is used. Note for example that instead of writing E:dle we have aredie 'He will go (today). The first comes from southern dialect while the second is frow Northern dialect. The second form is used in bcoks.

The written word has done a great deal of harm to the small dialects. This is esnecially true of the bible translations. In all the region of our etudy all the books are written in the two major dialects. This means that the language of the bible is that of the two dislect.

Everywhere, including soms parta of $1!u r u$, these two dialects heve beec taken as the religious dialects. The readings, the singing and even preaching (at times) are conducted in some variety of these two dialects. speakers of small dialects have therefore accepted these dialects as their religious language.

Another thing that has helped the spreading of the ajajor dialects is the teaching of ather tongues in lower prinary classes. In all the areas of our atudy the teaching of mother tongue means the teaching of the two western dialects. All young language learnere have to learn whet is popularly known as 'Kikuyu'. The leareing of 'Kikugu' takes place in echoole while local dialects are learned at home.
$A_{B}$ a result of learning the written language in schools all small dialect speakers have acquired two dialects. These are their local dialect and the two major dialects. They spesk some form of 'Kikuyu'. Those who speak the written dislects, howerer, slaim ant to understand the small dialccts.

From what we have said about these diaiects, one sees that lot of pressure is exerted on minority dialect speakers by the major dialect speaking people. Note that the major dialects are the basis of the standard language, are the basis of broadcasts, are dominant in numbers etc. The question of numbers is especially crucial to those living outside their home districts. Before discussing the role
of numbers in language use. Let us look at the following 1 gures 1.0. 4.

The 1969 census revealed the following figures of Kikuyu, Emu and Mbeere.
4.

Group Coast N. Eastern Nyanza Nairobi Nakuru district

| Kikuyu | 19,462 | 699 | 5,933 | 191,367 | 169.363 |
| :--- | ---: | ---: | ---: | ---: | ---: |
| Luau | 842 | 31 | 83 | 3.223 | 303 |
| Mbeere | 116 | 8 | 15 | 259 | 19 |

Figures given in 4 have serious linguistic implications. The implications are that small groups are always small hence outnumbered everywhere. Socially the speakers of small dialects are always pressured by the majority to speak "Kikuyu' Even the other small dialects 1. $\cdot$. Ki-Gichugu, Ki-Ndia and Ki-Mathira have the same tupe of relationship to the two major dialects. They are always represented by minorities.

Pressure on the small dialect speakers is most serious in institutions of learning. These are the places where minority dialect speakers are often asked about their relationship to major dialect speakers. One of my informants who is

- fInal year student at the Univeraity of Nairobi tola me of her being asked if she was a true Kikuyu. The question came from speakers of western dialects. This student, who speaks K1 - Nadia, did not know what to say.

```
Sonetimes these ainority dialect speakers are insulted by their peers. I talked to some studente froa Kanvenje Teachers' College who told we that they roferred to Ki-Ndia and Ki-Gichugu speakers as makamo 'uddors,' which is a way of sajing that thej cannot pass for either 'Kikuya' or 'Eabua'
```

## Footnotes to Chapter 1

1. As used here the word 'Kikuyu' is liaited to speskers of western dialects. 'Eabu' combines both Embu and Mbeere into one group. These meanings are linited to this chapter.
2. For those students both Embu and Mbeere are called 'Embu'.

## CHAPTER II

## MORPHOLEXICAL DIFTERDNCES

2.0.

If our linguistic theory is to enable us to write
grammars that are explanatorily adequate it aust have enough constraints. These constraints vill onable ue to write rules whose notivations are easy to see. In order to show the motivations of each and every rule that we write we have to divide our eramar into different components. The reasons for the divisions are easy to see especially when one compares a muncer of rules. A comparison betweer, syatactic sil a phonolofical rule shows that each of these rules has its own motipations. In order to show the different wotivations of differeat rules we divide our gramar into the following componentsi-

1. Phonological component.
2. Morphological componeat.
3. Syntactic component.
4. Semantic component.

These components will only be possible in a gramar 2ike N.G.G. which separates phonological from morpholozical rules. These types of divisions are exeaplifiod in the vorks of Fennewarn and Hooper given in the bibliography. For the division between phonological and morphological components see Hooper (1973).

#### Abstract

In some generative schools the above components are not distinguished. In the American Standard Theory i.e. Transformational Generative Grammar, gs exemplified by Chonsky and Halle (1968), there is no division between morpholocical and phonolocicel components. The two components are grouped together in one component which this gramar treats as phanological. For the Transformational Generative Grammar (hence T.G.G.) the above four components will be reduced to three.

In N.G. . G. the four components work in conjuction with each other. One component lills certain information on which the next component actseg. the phonological component will not play its role in generating surface structures unless all other components have filled in the necessary information. These components are therefore separate but work together.

This chapter will discuss the morphological differeaces that exist between the dialects of our study. We aball linit our discussions to that level of difforencen anlese it is necessary to explain a given change by ueing phonological evidence. This may be necescary where norphological differences may have been atarted by phonological rules.

### 2.1. Lexical differences

Certain lexical differences play an important roie
In fixing dialect boundaries. Coe can bo easily detected
as a stranger by using lexical itema his/her hearers conaider to belong to another dialect.

In order to exemplify what in want by lexjcal differences and to show why it may, at tines, be embarrasing to use a given vord we have the examples iu 1. Thege examples came from list of lexical items that wore tested in all the dialects. The words are given in appendix 3 . These vorde were chosen because they shoved the most serious differences.

For a sample of lexical differences we have the lolowing examples:-

As stated earlier these words come from a list of fifty words that were selected from a total of six hurdrec words. No percentages are used for examples in 1 because the number of items used for the lexical lest is too small to be the basis of any weaningful percentages. As these Ltems show the dialects are very closely related.

The above vords are not in any way unasual. They are the words that one inds in everyday mage. It is therefore not surprising that one could easily be heard using some of them even when people of different age fets nay be present. The most unusual vord for sost poople of this region is no. 6. This word means 'rape' in most parts of $S$. dialect. In the rest of the region the word teans 'take hold of'.

When a speaker of any other dialects sajs guta mwana 'take hold of the child' people of $S$. dialect appear most embarrased. To them that is naughty if noft otupid. They are quick to ask one where he/she cones irom. Usually they do not explain why they ask that, they siaply keep quiet. If the audience is a mixed one, i.e. parents and children, the word is highly resented.

The most embarrasing pair of words is 4 and 5. Note that the word for tail in Mbeere is the word for penis in Bron. The same relationship exist between the Gichugu Ndia group and the western dialects. One finde himeelf embarrased when he asks people what they call, saj tail,

#### Abstract

in thoir local dialect just to be wet by hostility and refueal to answer any other questions from him. The same happont when one says, 'the tail is $\underline{X}$ In dialect; What do you call it here?

I found myself in such a situation wher I aked ay Eabu informant to tell me what she would call a tail. She seomed not to remember so $I$ began to give her the names given by other informants. When I mentioned molude she became so embarrassed that $I$ was forced to skip the word. In Gichugu I asked an old woman to tell me what they call a tail. Her answer was that she was tired and that I had too many questions. When I realised that she was avoiding the answer I asked her whether she would answer other questions if I skipped that one. She replied that she was willing to asawor other questions. My informart from Nidia (an old man aged over 60 years) replied that the word for tail, 'mixes with male private part in Kikuyu' thus he was not willing to say it.

[^0]Such quick conclusions and statements such as 'You are from Nyeri.' correspond to the Americans' "You have an accent." Nobody seems to realise that he too has an accent dopending on who is making the judgenent. To Gichugu - Ndia opeakers everybody who doee not speak the two dialects or Ki-Embu and Ki-Mbeere is Mokabete i.e. Pron Kabete which means that he is fron the western dialects. To Eabu - Mbeere speakers anybody who does not speak any one of these two dialects and who also does not speak Gichugu is Mogikuu i.e. Mkikuyu. To the vostern dialecta' speakers everybody else is either from Mathira or Bubu. To then Gichugu, Ndia and Mbeere do not count as different dialects.

All the above names are different ways of saying. 'You have an accent or you are different from us. Of course these statements are not bused on one component of grammar. They are based on all components and features of Iinguistic variation. I remember askin one Kiambu informant what he considered to be typical Nyeri dialect. He answered by pronouncing words with ( $t$ ) and (d) e.8. (moté) 'tree' (Mo:ndo') 'person' etc. The way he pronounced these words was very much like the Northern dialect. His poiyt was that these sounds are produced at retroflex, 1.e. in Northern dialect, but with more of alveolar articulation in $S$. dialect. For this informant the point of articulation was more crucial than lexical differences.

### 2.2.1. Morphological differences.

In this section we shall deal with the differences that exist between the dialects in as far as morphernes are concerned. The word morpherne has teen defined in many ways. Traditionally it was used to mean the palest unit of meaning. It has also been called a unit of distribution and some other people would use morph instead of morpherne. We do not feel that a definition is necessary for our purposes. We shall not therefore join the list of those who have defined it.

The reasons for the use of the term worpherne genomes obvious when we start. exemplifying ard diccussarg nits of meaning. Whether one calls them morphs or morpinenets in not ancessary. What is important is the face that some of these units are different in different dialects.

In 3.1. and 4.1.2. we have stated that Gichugu and Nadia are very similar in a number of respects. These include sound structure. In this section we shall show the different morphological structures that exist between these two similar dialects. This is therefore on of the most important sections in establishing the divisions between these two neighbouring dialects. Other section include 4.1.2. which shows some differences in phonological rules.

### 2.2.1.2. Positive Tonses:

#### Abstract

In this section we shall deal with negative earkingtenses only. The reason for doing this is that certain morphemes, -.g. those marking persons, have different allomorphs depending on whether we use negative or positive tences (cf. examples in 2, 4 and 9). In order to give a proper coverage of these alloworphs it is necessary to consider the tences separately.

In S. Mt. Kenya one finds wany morphemes that mark tenses. In this section our discussions will be, wainly, focused on those tense morphemes that help us in fixing dialect boundariea. A few tense marking morphemes will be discussed in order to show that these dialects are in one group i.e. the whole region belongs to one linguistic group. There will be some morphemes that will be cited because they have extended their domain in some dialects but not in all.

Among the tense morphemes that have grouped whole of S. Mt. Kenya into one linguistic region are:- (1) the progressive tense - ra - (ii) the past participle -a(iii) the immediate future -ko- and the distant future -ka-. All these tense morphomes are the same in all the dialects. To exemplify this wo have the following examples:-

## Gichugu

no nda:rja ne wa:rjé njárjà
neaderarja ajorárja
njárárja
néggórja ajokorja ojákórja
negga: rja njoká:rjá
njáká: rja

Ndie
We dielects
nò ndárrjà né ndárjà
4. vascin ne vists ajárjá
ajarjas
néndérárja néndérárjá njórárja njáráry njárarja
náiggórja né:grórja njokorja njakorja
néggárjá négrárrja ajoka:rja njákárjà

I an eating.

You are catine.
He is eating

I will eat (now)
You will eat (now)
He will eat (now)

I will eat (now)
You will eat (now)

He will eat (now)

The tense narker in (a) is -a-.. The first (ne) is a separate morpheme which has different uyntactic functions which are not relevant to our study. The $n$ - or ad- that follows (ne) is a marker for fist person singular.

In (b) tense is marised by -ra- while in (c) tense is marked by -ko- which changes to (go) after n-. In (d) the tense is marked by -ka- which changes to (ga) after $n-$.

Examples in 2 show that the four tenses are marked by the same morphemes in all the dialects. There are, however, changes in both tone and the surface realisations of the personal pronoun For further inforaation on the surface differences see 2.2.3. and 4.2.4.

Among the positive tenses that show surface differences are the (unmarked) past tense -ire. The aid future -re and the verb to be -re-. The term unwarked is used here means that -ire is the muot general past tense market. When -re occurs as the only tanse barker it is suffixed to the verb-root. In such cases this morpheae stands for past today e.g. akgm-irc haha 'he slept here (bafore yeatarday)

This unmarked past tense aorpheme surfaces as -erE in Labu, Mbeere and Gichugu if the verb-root ends in /e/, e.g. 3a and 3b.

The above differences should be accounted for by the phonological rules. The three eastern dialects have a marger of /e/ and /i/into e: We have given this change here because it helps to separate Ndia from Gichugu.

In S. Mt. Kenya this tense is marked by -re-. The eastern dialects including Ndia do not have this tense in positive structures. In negative structures this tense surfaces in idda and in western dialects (cf 2.2.2.).

For the eastern dialects this tense has been replaced by the unmarked (most general) future tense marker -kaThe differences between the two dialect groups are as shown in 4 。

```
Fron examples in 4 it is clear that the mid future tense -re-has disappeared from the eastern dialects. Its disappearance has reduced the future tense morghemes Prom three to two 1.e. from -k.o-, -ra- and -ira- to -koand -ka-. This chauge seed not be derived hy a rule. It should be assumed that these eastera dialects do not have this. (-re-) tense in their urderlying represertations.
```

The western dialects have kept this tense morpheae unchanged. If our grammars are to reflect the intuitions of native speakers of the languages or dialects for which

#### Abstract

they are written such morphological differences must be revealed. This statement raises the question of whether or not the dialects have the same underlying reproseatatione. This question is answered in chapter 11 of of the study.

### 2.2.1.4. The Verb 'to bo'

The morpheme that marks the vert to le is -rem. This morpheme hae been reduced to -e- in a auger of dialects. Only Mathira and Northern dialect have not reduced this morpheme. Jor the purposes of extriplifieation vo have examples in 5.
5. Mu Mbeare Gichuru-Ndia MathifaM. S. dialect alone

Note that in Babi, Noerre, Gichugr, Ni an Southern dialect there is no liquid before -on Except in Enbu a combination of / ar o/ has collapsed into $[\varepsilon]$. This is not relevant to our present discussion. The change that has occurred in the five dialects can te accounted for by rule 6.
6. In Imbu, Mbeere, Oichugu, iNdia and S. dialect - re $>$ -

This change can also be accounted for by a phonological rule (cf. 4.3.2.4).

When the above change is accounted for en phonological grounds certain problemes arise. Note that in 4.3.2.4. this reduction is treated a liquid deletion. This liquid deletion has not applied to -re- class 5. prefix. The only dialect in which liquid deletion has applied to class 5 prefix Mbeere (cf. 2.2.4). For the Sourthers dialect. for which liquid deletion was formulated, the liquid is deleted when the root begins a consonant egg. income 'big (cf. 5) but rjega 'good (class 5)'.

The reasons for rejecting rule 6 as a phonological rule are revealed by the list of class prefixes given in 2.2.4. together with the above arguments. These leave us With only one alternative i.e. 四orphological reduction. By morphological reduction we mean that what is reduced is -reverb to be but not every occurence of -re-. In order to limit this rule to the morphological level of our grammar the morphological information of (+ verb to be) mut be included in the rule. This means that only one morpheme is affected and no other -re-.

If the reduction was a phonological rale with phonetic motivations all liquids before / / would be reduced. Failure to have such a general rale shows that this is not a phonological rule.

It ahould, also, be pointed out that this norpheae hee a number of different arrface meaninges Apart fron being the verb 'to be', it can aleo mean, at, fith or in poesescion of. The implied meaning wll dopend on the context in whioh it is neod.

### 2.2.1.5. Negstiva Toncen

In negative etructures Gichugu is seen as the odd dialect in the whole region. This dialect has the largeat nubber of divergencies from any other diadect. It has the micious unber of negative tonse barkers in thio region. In the examoles given in 7 -tiofta-starde ior 'not' 1.e. aegative. The gloso given is the tease negated by -ti-/te-.

1. Bobn Mbeere Gichagu Ndia Y. dialecte alosa
2. ti-ra ti-ra te-ra te-ra ti-ra progressive
3. ti-na ti-ne te-ra te-na ti-na past participle
4. ti-na ti-na te-na te-na ti-na paot today
5. t1-na t1-na te-na to-na t1-na past yesterday
6. ti-a-irc ti-a-irと te-a-ircti-a-ircti-i-ire past distant
7. ti-a-na ti-a-na te-a-na te-a-na ti-a-na past participio

| 7. ti-ko ti-ko te-ko te-ko ti-ko | sma. future |  |
| :--- | :--- | :--- | :--- | :--- | :--- |
| 8. ti-ka ti-ka -to | te-re ti-re | iuture todaj |
| 9. ti-ke ti-ka te-ka te-ka ti-ka | future (aictant) |  |

Fron these tenses it is olear that eren though Oichagu and Ndia have identical sound structures the same is
not trae of their morphological etructures. These two dialects have 'te' while all other dialecte have -ti-.

The change from eti to -te- in Gichugu and Ndia ia not due to a general rule of vovel lowering. The existence of a general lowering rule is diamiseed by ench worde as oliaa 'hole' $<$ •re-rima. Tbe lowering must have affected a number of morphemes only. To generate this -te- from ti we have rule 8.

In Gichugu and Ndia ti $>$ te.
Enle 8 is mot phonological rule, it is a diachronic morphological change.

To exeaplify the surfacing of all the morphemos shown in 7 and to do it adequately would take a lot of space and require many examples. Wo foel that this in not necessary aimply becanse no single atruotere wll pass through all the above tenses and dialeote without undergoing sone changes. We have thorefore chosen to pick out one etractere and ran it through all the tonaes. The atreoture will not eurface with the nogative tonase as shown in 7 but will reveal the necoseary ileleetal differences. One of the changes from the anderlying reprecontation is the voicing of /t/into [d]after mo For this roason /a-ti-/ vill surface as [ndi]. This and other changes that may be noticed will be revenied in 7.

## G10 1

'I as not atine'
'I have not extsa'
I did not ant ${ }^{\circ}(\mathrm{m})$
I did not ent'(yo)
1I did not cst'(I a)
'I nover ate.'
-I will not eat'(N)
' I will not eat'(T)
'I will not oat'

As atated earlier Gichugu bas reduced its negative tense morphemes. For the past tonse structures this dialect has generailzod the nae of -te-ra- in aearly all the etructures. The only past teabe morphene that hes not beon roplaced by -te-ra- is the distant past i.e. past beyond jeaterday, which is retained as -toma. Some informante said they would use -te-na for pant (limited) tense e.g. [ndánárjá] 'Ro did not eat (during that period). This, could also mean, 'He hae never eaten. For the surfaoing of -nd- instead of a-te, which is the expected form see 4.2.4. and 2.2.2.

According to the above etructures Mdia in eleser to the wester dialects than to Cichugn. These tonce morphenes reveal a clear divicion betveon Gichnga ane Ndia dielecte. Tone too playe an important role in distinguishing these two dialecte froo each othor. In general Ndia tones do not agree with oither those of Gichugu or the western dialects. This aay be due to the fact that Ndia lies betweon the two main dialest groups 1.e. eastern and vestern.

In conolusion it ahould be noted that oren though the two dialecte of Oichugu and Ndia have identical sound structures they differ in their morphological stractures; For Gichugu there is a tendency to generalize one tease combination for all past tense stractures. Ndia does not have this tomancy. A similar difforence
was shown to exist in the lexicez (ef. 2.1.). There were some of the reasons for the separation of Gichugn and Ndia as different dialects. To group these two dialects together vould have necessitated the positing of a number of abetract representations. Since our theory aime at reducing abstraction in the underiying representations the grouping of these two dialects as separate is justified.

### 2.2.2. Porsonal Pronoune

When talking about personal pronouns one eust diatinguish between bound and independent allomorphs. The distinction is necussary because they do not behave the same. Bonnd allomorphe behare like clase profixes In that their aurface realization deponds on the stracture of the root. Apart fros that the morpheme markiag the person will depend on wet type of a root is reod. If the root is an adjective wo have one type of marker and whon the root is a verb we have enother. All these wil bacose clear when we oxamblify theli.
Before wo examplify naj of these aorphemes and alloworphe wo should point out that any table of worphomes and allonorphe that will bo given will zot be sble to reveal all surface forms. Sowe of the surface forms can only be generated diachronically. Such diachronje forme will be shown and tiselr origins discuesed.

With the above comente ia $\begin{aligned} & \text { ind we ere now in a }\end{aligned}$ position to oxomplify the dinlectal difforonces that exist in these morpheres. The following is what is to be expected as indepeslent perscinal p or snas of 3 . Mt. Konye dialocte. Thes bave no diforent gurface forme:

$$
\text { As stated above these morphemes } \wedge^{\text {realizod as }}
$$

shown when they occur in isolation. In bound etructures sone of the above persons are marked by allghtly different allomorphe. In their most general forme the bounc allosorphe can be sumarised as follove (in verbal etruotures):- (see 11)

When profixed to the adjectives the firet person sg. ourfacen ac no- in Eabu and Mbeere but ae ado- in all othor dialecte. All other peonouns are profixed to -re- 'verb to be' in such positions.' This seare that the first person plaral will surface as -too in Mbeere and S. dialeot and -to-ro- in all other dialecte. The -rois the verb to be.

Let ue now go back to our independent norpheane in 10 and concider their historical developaent. Fron the present dialectal forms we can reoonstruct the following as the proto roots of personal pronouns in 8. Mt. Kenya. $=$

| 10. | Pereon: | Eabu | Mbeare | Gichugu |
| :---: | :---: | :---: | :---: | :---: |
|  |  | - |  |  |
|  | 2 tat parcon | sg. nge | Pjor | neto |
|  | " $\quad$, | p1. twe | dvo | twi:o/duso |
|  | 2nd person | د¢. ข¢́ | พย์ | weo |
|  | n n | p1. Euć | mió | -wi:o |
|  | 3 med person | esore (mi) | * < | แร์ |
|  | - ${ }^{\text {a }}$ | a. |  |  |
| 11. | Parson | Eabu | Mbeere | Gichugu |
|  | 1 et porson | ag. no/a | nofn | n |
|  | " $\quad$ | to | to | to |
|  | 2ad poreon | $5 \cdot$ | - | - |
|  | " $\quad$, | p1. ${ }^{\text {- }}$ | -0 | ш๐ |
|  | 3rd parson |  | $\cdots$ | a |
|  |  | pl. |  | ■® |

| Ndia | Mathire | Yedialecte | G208B |
| :---: | :---: | :---: | :---: |
| - $\ddagger 0$ | njó/níió | aje | $I$ |
| 1呺 | 1́lue | Elue | us |
| $\checkmark$ E: | wélw | Wét | jou |
| inwé | ifue | ipue | you |
| - 2 | 凶غ์ | - ̇̀: | hin them |
| Ndie | w. dialecte | E 91088 |  |
| n | n | I..... |  |
| to | to | v |  |
| - | $\bigcirc$ | you... |  |
| -0 | mo | jou... |  |
| 2 | a | he |  |
| - | - | they.. |  |

Fron these proto - forme the independent eorphenes were generated by adding the reflexive morphene -e- to the root thus getting /ais/, (tae/, */vge/mue/s - /reo/ */Bao/ respectively. For the second person aingraar and the thirai porsca singular the only distinction seema to have been tone. There secms to have been a problem of distinction between these two thus lengthening being used to show the difference. Even that did not solve the problen. What seems to have been used as distinguishing factor is vovel collapsing and loss of -o-. Some dialects lost this -e- while others collapsed - C - and -e- into -E:-, in one number and not the other.

The Gichogr dialect seens to have deviated fron the rest by using -o- as a suffix to parsonal prozone. Inis -oin ilkely to have cone from the relative -o-. The -erelative is found in olasson $1,3,14$ ote. Wote that Gichugr eofrod the problen of diatinguishiag second person eingular fron thisd poraon aingular by adding this -oto the second person but not to the third. To as this should be a triger to show that speakers had some difficulty in dietinguishing these two from each other.

For the third person plural we have a problen in that wo have - כ - and not - 2e- as the above discuseiza 1ndicates. The must plansible analysia vould be that [J] cones from 'B J́e. mhis is not a strange proposition eapecially when ve consider that "pachenges to "py $>V$ ว in the same region. For further C-ecussion and oxemplifications of this $\nabla 5$ see 2.2.4. According to this proposition $[j]$ comes from By relative and not from Bas.

The other point that wo ought to consider is why this [J́] should eurface as [mj] in Oichagn, Ndia and Mathira This ie dealt with in 2.2.4, under class profixes. The ancfacing of this nasal is analogical (cf. 2.2.4.).

In concluaing this section lot us consider why tu chenged to - du - in Mbesre Ndia and western dielecte. He shall, also, consider the change of mu to ma in the same dialecto. As indicated in chapter 3 we have certain"to that changed to /a/(cf. 3.1). These were mainly in roots that were prefixed with * of classes $9 / 10$ or lat person singular. We are inclined to think that the change from etu to du was either under the same influence of "n or on analogy to the change of some $/ \mathrm{t} / \mathrm{s}$ to $/ \mathrm{d} /$.

The change frow min to nu in a very strange one. If wo ascure, that this vas a case of palatalization ve shasl bave a crazy rulo that palatalizes $/ \mathrm{a} /$ before [r]. This type of palatalization is disqualified by the fact that the dialecte that palatalized $/ a /$ beforo [u]are the osec

```
with which we get /au/ today. The dialects that did not
palatalize */v/ before [u] are the ones vith this nu
    < "mu. Note that in sastern dialocts"kanua 'moutb"
has changed to kgnva while vestern dialects have kanua.
```

The facte given above lead to the conclusion that the change froa "mu to /nu/ cannot be explained in a clear sound change. Whatever night have caused the change it it not likely to be a phonological change. It may have been some type of borrowing. Even this is not explained.

The nost likely source of this change is Ndia where both nue 'drink' and kapya 'mouth' are found. This dialect maj have had a rule of palatalisation that was wrongly generalized to "na and vich vas later borroved by other dialecte. As stated above ouly Rdia has both gua and kanen while other dialects in the west have kanua for 'month' and mME 'drink'. Despite this me cannot conclusively clain that the change fron "m to me began in Ndia.

Note that this change reveals that not all changes will be phonologically natural. Even though nost sound changes are caused by phonologically natural rules ve ahould not fail to see the unnatural ones. Sone changes like the above may be (totally) phonetically unmotivated.

Haring discussed the changes affecting independent norphemes let us now turn to the bound allomorphe. As
ve atated at the begianing of this section the surfacing of bound alloworphe depeads on the initial sound of the erb root. To give an exanple of the different surface forme we heve the following realizatione for the first person eingulers-
13.

| Eubu | Mbeore | the rest | initial sounds |
| :---: | :---: | :---: | :---: |
| n | n | n | alveolars (cons.) |
| $\square$ | - | - | labiala |
| $\pm$ | - | - | labialdental. |
| ค | $\boldsymbol{8}$ | ת | palatals |
| 4 | 9 | 9 | velars |

The above forms are sychronic and are discussed under phonological rules (cf. 4 4.1.4.). The reasons for discussing the above changes under morphology will become clear when we exemplify them in actual worde. Before we exemplify these forms we should point out that there are wany instances of rule morphologization. 'linw morphologized forms are those geterating [y] for the first person eingular even when no jillabial soanc is arailable.

In cases where [m] cannot be genereted froa on uxderlying
labial environment we coneider ite seneration as boing morphological in synchronic gramar i.e. it is diachronio. The following structures will help to revenl the differont typen of morphologization that heve ocerred in the dialecte of thic atudy:-
(1)
(11)

日- 日ra
(i1i) a-nga
(17)

B- Ba
(v) p-ina

Looking at the differences between the dialects and the differences between the underlying representatione and the surface forme certain changes becone very cleare It is obvious that the above roots had different initial sounds froe those that are there today. This is true of nost of the roots from (1) to (x). These roots had a labial consonant as the iaitial sound which vas later 1ost.

After the loss of the initial comsonants the verbs were retained as if the bilabial consonant vas not lost. For the generation the surface foras the verb were warked as * $B$ roots. The generation of surface forms was based on a class of norpbemes and not the initial sonkd. These are therefore morphologically gerereted forms and not: phonological. Their being morphologically generated justifies our discussing them under morphology.

For dialectal variation note that the dialects weet of Eabu have generalized all the vovel initial roots as if they had a palatal consonent in their initial positions. This means that after the loes of the labial consonant the roots wore reanalyeed and clancified ia the palatal class of roots. Evidence for there haviag been rule sorphoiogisation is not hari to get. Is the dielects west of Imbe we have examplee exch as mbigwerj/mbunvers 'hearing organ'. This comes from "/h- Bigw-oro/.

Since the root is igue 'hear' the only justifiontion for baviag ab is through some diachronic ${ }^{-}$B. The asmeacing of gb- from "b-B in, todey, a rare phenomenon in western dialecte.

The above two dialeot groupe i.e. the ab-group and the at-groap have each morphologiged the derivation of the firat person singular marker but in difforent vaje. Onderlyingly the ny group has no palatal fron whicl thic [f] comes and the mb-group has no underlying bilabial sound from which this $[\mathrm{b}]$ comes from. The difference betwean the two groups is that the eastern group i.e. b- group generates the surface forms from ${ }^{-B}$ roots while the western group i.e. nj-group has analogically levelled all vowel initial roots as $/ 8 /$ roots. For the eastern group the old * roots have been retained even after the 10ss of B. The sane is not true of the vestern group.

The purpose of the above discussion has been to show that we cannot, alwaya, generate aurface forms by phonologioal rules. The only things that phonological rules womld generate are the different realizations of $/ \mathrm{n} /$. Note that this morphologization of phonological rules is one of the waye in which natural rules get denaturalized.

The second person piural morpbese has a very
interesting dialectal variation. This morphene is -nom
in the prefix positions of verbs. In most parts of
S. Mt. Kenya this is, also, the objective Marker of the same person and number. We use nost because in
 The following oxaples show this -me- objeotive.

In all other areas of this reg 200 the above -me- wuld be roplaced by -mo-.

One interestiag thing about this -ier is that in some areas ouly women and children use 1t. This is especinlls true of Mugoifi location where even ay womea informante agreed with this clain. In all other areas including Njumbi and the area south of Sagana town this -ae- objective is need by all apeakere.

The source of this -me- objective cannot have been aporadic. It cannot also be an isolated ianovation. These two things are ruled out by the vastaess of the area in which this -no- is uned. The area spreade in the wiole of Murang'a from North to sonth and fros vest to eant. It mest have been a feature of a vast nenber of apenkers.

The fact that there are indications that this type of feature covered the whole of Murang'a leade to two poseible
origins. The first origin may be from some earlier people who occupied the area bofore the presont occupants. The second origin nay be a variety of language or dialect brought by some new arrivals into the ares. Of these two the Pirst seems to be more attractive. Note that is this feature came from the same source with other dialects it vould have been detected outside Murang'a, but it has not.

There is another plural marker for the second person. Tbis is the suffix $n i$. This norpheve has been reduced to -i in all the dialects west of Gichugu. The following conparison revesle the reduction:-
16.

These examples shov jet another distinguishing factor between Oiohugu and Ndia. In discussing this reduction under morphology we imply that it is not phonologically notivated. We have other occurences of (ai) that are not rediced e.g. nogeni 'visitor'. To generato this rolaction fithout reducizg other typee of/aj/we bave rul. 17.

Rule 17 will only reduce suffix $/ \mathrm{aj}$, and not ans other. Since $[n 1]$ of mogenf is not a suffix it will not be subject to rule $9 \%$

In conclusion let us go beck to the 3rd person plural marker. At the beginning of this section wo claimed that the plural marker in the proto language was Ba. Without further discussions or exemplification there is a likelihood of getting some objections. Some might voider how we got this *B that is never realised in the present day surface forme. For tho oe who maj want to disagree with us we hope that the following example Iron There will do:-

To us the above structure cones from $/$ /ado Bate pro/. For some reason this "Ba got an $/ \mathrm{n} /$ preilized to it thu c deleting * $B$ through the Ganda law. Note that Mbeere does not have "as for this number which we saw to be present in Odchaga, Nadia and Mathira.

Further evidence for there having ten "B in this class is to be found in the comparison between -V? and - Jin Paba. Vo stands as the relative for place while 2 stands for the relative people. Considering what we aid about ${ }^{B}$ deletion it is obvious that the presence of ${ }^{\circ} B$ 1. unquestioned (cf. 3.1., 3.1.2.)

In this section we shall deal with the present day demonetratives of $S$. Mt. Kenya (see 19). Our aain concern will be to find out their origins and the sound changes that have affected them. By origins we mean the proto forme of the present day demonstratives. For a list of the three deaonctratives see the attached exaples (19). The examples given in 19 deal with nouns classes exenplified ia this section.

To begin with let ue look at the $-n$ suffix. This domonstrative is found in other $B_{a} n t u$ langages as well. It occurs in some old forms Kiswahili dialects e.g. heyano 'this (cl. 1), hikino 'this (class 7).' In S. Mt. Kenya this auffix has been lost in many classes. The only classes that have $\frac{i}{i}$ tained this surfix without dialectal difforences are classes 4 and 9. In nany other classes this suffix is lost. The dialects that have retained it in a fow classes will be shown later.

Por classes 4 and 9 we have the following exampless-

| (i) mete | on | these trees (cl.4) |
| :--- | :--- | :--- |
| (ii) mesre | enj | these bodies (cl.4) |
| (iii) poimba | onj | this house (cl.9) |
| (iv) go:abe | onj | this cow (cl.9) |

## The dononetratives

(1) near the sooaker

| Clase | Dabu | Mbeere | G1. chugu | Idia | W. dialects | Glose |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 4 | -n | -n $=$ | -n | enz | An) | the.ce |
| 8 | 103 | 10\% | 1 tsi | itsi | \& | these |
| 9 | - 27 | ens | - 0 | 日 0 | ena | this |
| 10 | in | - ${ }^{\text {a }}$ | 1tsi |  | 161 | these |

(ii) near hearer

| 4 | -j2 | -j2 | -jコ | -90 | - 2 | those |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 8 | 181 | $1{ }_{1} 1$ | icmi | 1tei | isi | those |
| 9 | -j2 | -12 | -j2 | - 3 | -j2 | that |
| 10 | 1513 | 181) | itaio | itedo | 1512 | those |

(111) avay fros both apoaker and hearer

| 4 | elea orea elea elea orea | those |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| 8 | ilia iria ilia ilia iria | those |
| 9 | elea orea elea olea orea | that |
| 10 | ilia iria ilia ilia iria | those. |

Those sxanples will have the same sound otrectures is all the dialects of S. Mt. Kenja. The only difforence to be experieaced will be in tone patterne ef. Bactern dialecte have ǵn while vestern dialects have onj for both 'thece' and 'this'.

Babn and Mbeera have two other elasses that take the ouffix nj. Whese are classes 8 and 10. For tbese
tvo clasaer we have these examples:

In other dialects the demonstratives will be either itsi or ifa. The Pirst occure in Gichuge and Ndia and the secoad occras in western dialects. In other vorda these other dialects do not use -n suffix in classes 8 and 10 .

For anbu and Mbeore the difference between clasees is marked by the prefix. For classes 4 and 9 the prefix is [ © ] but for classes 8 and 10 it is [1]. Note that both class 4 and classes 8 and 10 are plural classes thes [1] cannot be interpreted as a plural marker. The same is true of [e].

The differences between the above dialect groups 1e. Enba and Mbeere in one group while the other dialects stand together are not liaited to classes 8 and 10. Other clacees reveal similar differences e.g. class 5. For this class see axacples in 21.

## Enbu-Mbeere

| 21. (Madiga) mama maja | "these (stores) cl. 5 |
| :--- | :--- | :--- | :--- |
| (Magona) masa maja | 'these (bonkejs) cl. 5 |
| (Maru) mana maja | 'these (knees) cl. 5 |

Haring looked at examples in 20 and those of 21 we can now go back to the question of sound changes that resulted into the present demonotratives. It is obvious from these exanples that at one stage these dialects had two types of demonstratives. The first one wes aj euffix that wes used for all or for most of the clasees. The second one vas the duplication of the clas prefix. The duplicated clase prefix functioned as denonetrativo. In Prbu and Mbeere the iret deanetrative is etill iaportant while in other dialects the duplicated profix han gained proninence.

After the development of the deplicated prefiz as an inportant demonatrative, certain sound changes took place which led to the present day forms. We shall come to these changes shortly. After analyzing the existing demonstratives and class prefixes wo can reconstruct the following as the proto-prefixes:-
22. Class $\quad$ Prefix

| Clase | Prefiz |
| :--- | :--- |
| 9 | $n i$ |
| 10 | $n i$ |
| 11 | vo |
| 12 | to |
| 13 | ka |
| 14 | Bo |
| 15 | ko |
| 16 | Pa |
| 17 |  |

Of these classes $1,2,4,9$ and 10 profixes are not used me demonstratives in any of the dialects. Of the realning 13 prefizes 4 have undergene changes. These are for classes $2,8,14$ and 16 . The changes affecting these classes have resulted in the above dialectal variations (cf. examples 20 and 21).

The changes affectiag olasses 2 and 14 are identical. These can be stated in the following manner:-

The ábove changes show the lose of a roiced bilabial Pricative and the gliding of the aace Ificative ia the intermeatic poitions. The is lose is diamesed in 3.1. and 3.2.2. The gilding needs a fow comente.

It is not necescary to have had fliding taking place 1a all iatervooalie positions. It night have happoned betwees two low vovele 1.0. 日-a. It maj alco have mappezed between two identical monfront vorela only. Whaterer the oavifoments the change from ${ }^{\text {B }}$ to /j/is a crasj rele. It is one of those rules that are attested in langagea but vhich are unnatural.

After the gliding of ${ }^{\circ} \mathrm{B}$ between $/ \mathrm{a} / \mathrm{s}$ and the losa of the same sound in all non-nasal environments (cf. 3.2.2) wo could get glide insertion between certain vovels. This nay have taken place to the Bame onviroment that had lost a consonant. The claid we are making should zot be seen as if it is a strange and an ad hoc change. Note that in buou we do not havethis [J]between two /o/se.g. for the nestern dialects' ekojo. 010 etc Einbu bas gekoo. oo
 $/ \mathrm{j} / \mathrm{between} / \mathrm{a} / \mathrm{s}$ could, later, be generalized on analogy to clase 2 structure ie. BaBa>aja and BoBo>00>0jo on analogy to afa.

Note that the presence of $j$ in ciass 6 desonstrativo must have bean generated analogically. As exesplified in 19 프- vas reduplicated into mana 'those (class 6).' The dialecte vest of Imbu changed "Mama to 'raja' 'these clase 6.' In these innovative dialects -ja vas interpreted as the Feat for demonstratives while mas was interpreted ac class marker. For fabu and Mbeer the whole form 1.e. maga was a single moroheme.

In the above discuseione wo bave clained the historical reduplisation of clase prefixes in order to forn demonetratives, Now we turn to the diecussion on hov fifi 'these (classes 8 and 10), came into being. According to the table in
 into ${ }^{-B i B i}$. After this the noral changea affectiag ${ }^{\circ}$ B operated (3.2.2). There was, however, another change that seens to have occured and interrupted the changes affecting -B. This charce is as follove:-
24. $B>$ ts /-ia

Prele 24 generated the following etructures:-
24. Proto-forms attested forms Gloss

| - Biara | Biara | bear (child) |
| :---: | :---: | :---: |
| - Bi-ana | Biana | $\checkmark$ children (cl. 8) |
| - Bi-aku | biaku | jours (cl. 8) |
| Bi-aise | tiake | his (cl. 8) |

Rule 24 must have operated before " $/ B / B$ dropped out in all non-nasal onvironments. If $B$ less had taicen place hefore rul. 24 wo would not have gotten the examples in 25. What happened is that after rule $24^{\circ} B$ lose took place and deleted all the $/ B / s$ that did not alternate with rules-。

After ${ }^{\circ} \mathrm{B}$ loss the class 8 prefix becane[ii] 'these (c1. 8)'. This demonstrative is found up to today the speech of especially ing old people. In such people's apeoch one hears inaka if 'these bughes (cl. 8).' What seans to have happened is that class 8 denonetrative developed a

#### Abstract

ander of enrface forns. These were ai- for the olace profix mainly in nowne and in possescives, i- ac profiz on adjectives e.g. ite inf̂g 'bis chaire,' and fimally I1 as the denomstrative for the sane clase. All these varieties are to be found in this region.

#### Abstract

The speakers of these dialecta have followed a trend of minialsing these surface forme. The form that is Waning over othere is -tsi- or -ai- depending on the dialect. This is interpreted as the root for the denonstrative and is then prefixed with 1- to make itsi or 1fi. For Fabu and Mbeore -ind is used as demonstrative for this ciase and also for class 10. They lo however uae ह̂i- in the possessivese.8.

26. Mbori inj n . siac Whose goats are these? gaimbe inj ae Kiakwa 'These cows are mine'.

The vestern dialecte will always replace in with isibut everything else is the same. Here we see a case of paradigatic regelarisation takiag place at different raten in different dialocte.

Pron the above discussions and examples we note that the reduction of allomorphy within the (desonstrative) paradigm ia major force to be reckoned within language change. This force has led to the unnatural rule at - $8>$ ts or (rule 24). Thie rule 1s motivatod by the force of paradigatic regularity. It is not a regular sound
change that one finde in many languages.

To conclude the discussion of the historical development of the deaonstratives, let us consider the changes affocting class 16 demonstratives. Examples in 22 show that this clase had ${ }^{\text {Pa }} \mathrm{Pa}$ ita prefix at the proto-language atage. This prefix vae reduplicated to epapa to fora the denonstrative. Through a process of changes that wo crilled P-lenition (cf. 3.2.2) this form has becone aja ia Embu and Mbeere, aba in Gichngu and Ndia but haha in vestern dialects.

The reduction from "papa to ava and aBa, through p-lenition, operated differently in different dialects (cf. 3.2.2), In the four eastern dialects the procese of p-lenition deleted initial $/ \mathrm{p} / \mathrm{s}$ after they had reakened. This stage (of deletion) did mot occur in veetere dialecte. Instead of this cage the veotern dialeots changed the bilabial sound into a side honce $\mathrm{M} /$.

### 2.2.4 Monn claspification and class matelas.

In 2.2 .3 we touched on the proto-claen proilize. We also discussed how proto-class profiseo vere rodupliented and changed in the procese of the creation of the present day denonstratives. In this aection we ohall deal with the claseification of nouns and the present day clase markere.

In nost clasees nouns are classified on the basis of the concord (i.e. what is assuaed to be the concord).

#### Abstract

If a now nown is borrowed iron other langages it may go to different clasees in different dialecto. The general tendency, However, is to place all noune without cless pretixes in clasees $9 / 10$ unless they denote huma beings. This placing is only a tendency and not a general malo. If it was a general rale all dialects would put such nouns in the sane Glasser bot this does not happen.

#### Abstract

At times, a ney noun la classilied in a given clase due to the influence of what is already exiating in the dialects. A good exarple of such a noun is Burana 'pallorer'. (borrowed from English(Flannel) through Kiawabili -fulana). This nonn is placedin classes 9/10 in most dialects ont ia Sovthern dialect it is in clasees 14/6.

The reasons for classifying Burana in classees 14/6 1 is due to other noung that begin with the same sonnd and are in the same classes. Such nouns include Borori "country'. We also have Bundi 'tallor' wich is in classes $1 / 6$ due to the fact that it denotes humen beings. Note that Bundi is also, a borrowed noun i.e. from fundi (Kiswahili).

Is other dialects this noun ib placec in classec $9 / 10$ on the basis of the rendoncy that putB all nouns without clese prefixes in these two classes. These two different placiage mean that tre above coug has diflerent cless markers in difieront dialects e-8. Burana Mwua igond pull-over'. (in Southern dialect). In other diaiects the

#### Abstract

etructure vould be 'Burana njega' or gnuranánbege' depending on the dialects. In this caee the clase prefixes are eo- for Southern dialect and p- for others (with other changes $n>m b ; n>n f$ due to analogical levelling).

Before ve discuss other changes that affect prefixes let us look at the prefixes that exist in our region of study. Ia the following table some classes have two surface forme. The first one occurs in verb initial poeitions vhile the second one occurs in adjective initial positione (i.e. primary and secondary pronoune).

According to table 27 cortain changes have taken place. The first of these is in clase 2. In thic claes the verbs are profixed with ma- in all the dialecte. The same clase has a- as its mariser in the prefix positiona of adjectives except ia Gichugu, Ndia and Mathira whereme- is the generalized class marker. For these three dialecta etructures euch as ando maMurang'a 'peoplo of Muranr'a', are the nore while all other dialects vould say, ando a Murang'a. Speakers of the three dialects vould also say,
 ajanez -

When Gichagu, Ndia and Mathira people produce these form outaide their own areas they are imediately detected as strangers. The interesting thing about this mageneralisation is that it is seen as a Noeri thing especially by people from the Southern and sone parts of Northern

| ad chusu | Ndia | Mathira | Y. dialacts |
| :---: | :---: | :---: | :---: |
| a/80 | 2/mo | 2/00 | Noo |
| -a/a | ea/ma | ma/me | ma/a |
| $0 / 10$ | $0 / \square 0$ | -/mo | -1mo |
| -18e | -100 | -10 | -100 |
| re | re | 50 | 5 |
| -a | -a | -a | -a |
| ke | ko | ko | ke |
| 1/2 | 1/3 | 1/m | 1/n |
| n | a | - | \# |
| m | [ | - | a |
| 50 | ro | ro | 50 |
| ka | ka | ra | ka |
| to | to | to | to |
| no | - 0 | -0 | mo |
| ko | ko | ko | zo |
| Be | Ba | ha | na |
| ko | ko | ko | ko |
| ko | 120 | Lo | <0 |

dialects. People are often asked whether they oone fron Myeri but those who produce this type of etructure know that it is a Mathira (thing) Poature.

Other classes that show certain variations are class 1, 3. 4 and 8. These are the clesses thet have one fors for verbs and ancther for adfectives. Of all these classes only class 8 can generate the present day vowol through sound change i.0. i- $<$ Bi. The lose of ${ }^{\circ} \mathrm{B}$ in such positions is accounted for through normal scund change (cf. 3.2.1). In other classes, except clase 2 , the vowol initial positions cannot be generated through a clear sound change.

The vovele fond in initial positions of verbe in classes 1, 3 ond 4 are likely to have cone through certain unclear analogical levelliags. Mote that for all these classes we vould moed a rule that doleted "s in verb initial positions and not anywhere alse. Smal a mele would be ad hoc and unootivated. We therefore reject any ad hoc rule that deletes ${ }^{\circ}$ : in verb iaitial poaitione.

There is an important and interesting variation that is revealed by comparison of dialectal forms of clace markerc. A part from the differencee in prefixal forme ve find sone forn of double aarkers in one stracture. The second maricer seene to be incerted in the root. To 1llestrate this we have examples in 28.

Gi ohyer
j כisac
vวsade
taiכ:nde

- $2 \sin \varepsilon$

S．diaiect

Glos：

ココ：\＆
w ：小
＇all（olasa 9）＇
＇all（class 14）＇
＇all（class 10）＇
＇all（class 7）＇．

Bramples in 28 raise a nuber of questione. The firat question is how the $[a]$ in $[j \jmath p d \varepsilon]$ and $[j \partial$ indé $]$ should be treated 1.e. is it part of the root or is it a different morphene? The other question is what this sound marke if it is not part of the root. It is also necessary to ak whether this [ $n$ ] was lost in western dialects or not.

The question as to whether or not the $[n]$ should be considered as part of the root will be anewered in chapter 5. In that chapter ve shall look at the underlying representations of the varying dielectel forme. In this section we shall concern ourselves with how this [ $A$ ] eame into the above root. Note that the discussion in thic section is limitef to the diachronic devolopment and saye nothing of the synchronic status of $[\mathrm{n}]$.

A comparative study of other languages reveale an absence of this nasal in the above morphere. The mont Iikely thing to have happened was that the class 9/10 prefix vas incerted in the root for 'all'. This is rathor etrange because there is no other root that shows sigas of infix. All that vo cee are profixer and suffixee. It comld bo that the root for 'all' is unique in this reapect thes from ute to juts then jade/ jade or -364 3nds

[^1]meant that the $\{\mathrm{n}\}$ prefix could be placed of the before 2 or between 2 and tE. One dialect or a group of dialects nay have inserted the prefix in the latter position thus resulting into the present day root. At the present time [n] in this root is not separable fro u the root of the root.

The [ ${ }^{n} \mathrm{n}$ ] mast have been lost in the western dialects at an early tia. If tais in mes not lost the western surface forms should have been identical to Gichegu. Note that in western S. Mt. Kaye /at/ change to [nd]. At the tine this rule was introduced /at/ had already changed to viz. The lengthening of the vowel before /d suggests that a nasal was lost and that its place is retained by vowel length (of. 5).

For class 14 prefix Mbeere uses ko or o. The surfacing of $/ \mathrm{ko}$ as go is due to Dahl's law. This appearing of ko in class 14 shows that there has been an expansion of class 17 prefix. This ko refers 'to place' and also 'in a place.' It is not strange therefore that class 14 should have ko prefix.

If what is being talked of is in reference to a place -.g. Bororí 'country' then ko prefix would be appropriate. Note that Bórórí will take ko prefix but oru 'badness' will take o prefix. This reveals that these prefixes are used for their appropriate semantic moaning. It seems that ko is used to refer to places while abstract nouns

- 80 -

The clais that class 14 has been split into two is not limited to Mbeere. My grund-parente, who spoak the Northern dialect, $u s e$ ko for nouns like Borori and any other place noung but nee o as a olase prefiz for all slase 14 notne in demonstrative o.g. Boróri ojó 'this country' but Borórín gridé 'in the whole land'.

The o of ofo 'this' is derived from *Bo prelix through other sound changes while ko of goote 'all (place)', cannot be generated by rule. These two ezamples among others prove the expansion of the domain of ko-.

The other dialects have $\underline{o-f o r ~ b o t h ~ d e m o n c t r a t i v e s ~}$ and adjectives -.g.[Bóróri ojó wj́de]'all this land (in the whole lund)'.

### 2.2.4.1 Class prefix redaction.

Class profix redections heve oceured in clase 2,5, 8, 14 and 16. The rednctions have occured differently in difforent clesses and dialects. For clane 2, 8 and 14 the roduction occurod and apread to all the dialeots. For clase 8 only Babu has rotained $[1]<\cdot$ Bi, other díalects have lost both $B$ and except for demonatratives (of. 2.2.3). Pabu say ito in a wile othere say ite ment 'big chairs', (o/Bite BinEnc/.

The reduction of clase 5 prefix is goneralised in Mbeere only e.g.s-

According to my Mbeere informant /re/ has been reduced to in all environments. In all other dialects wo hare sone surface forms wi /re/. The re- reduction in

Mbeore needs a rule like 30.
30. re >e.

In other dialects the prefix re is reduced to [ $]$ if the root begins with consonant otherwise it remain as re. Eabu is not subject to any re reduction because re surfaces in all environments. For these (reducing dialects a rule like 31 is required:-
31. $r \bullet \rightarrow$ (fla $\rightarrow$

Rule 31 accounts for the data but its phonological motivation is questionable. To suggest that we bare a phonological rule that deletes $[r]$ In the above alviromant would be rather suspicious. It easels that the two sllomo pts here bean norphologized such that $[r e]$ is a prefix of vowel initial roots and 0 ] Cf consonant initial roots. These resulted from the change from re to - then to re doe.
32. */re/ / / / > r* /-v.

#### Abstract

Role 32 is more phonologically motivated than 31. This latter rule aohieves CVCV structure while sherte againct it.

The changes affecting classes 2, 8, 1h and 15 are aocounted for in mound changen (cf. 3.2.1). The sect of the prefix need no discuedione.

Ia conclucion we have to strens that there are other cases of morphologisation. A part from the claseifyiag of roots into "B roote etc., even vhen no ereh sound exiate today (of. 3.2.2), we have other cases that show norpholegisation. One such case is the derivation of such vords as:-

In the above discussions we noted that mb- is
generated by a morpbological rule. This rule is productive in Ki-Enber but not in any other dialecto. In other dialecte form in 33 must be generated by a historically sorphologised rule. This rule affecte a saall set of norphenes.

The difference between the dialects are as result of this historical eorphologised. Note that unlike in KiBba otier dialecta have no rule generating mb- $\langle\cdot / \mathrm{n}-\mathrm{B} /$.
dialects $m$ is no
In these (other) fonger soparable Irom 2nif. This aeans that the aingular of mani ${ }^{3}$ 'papils' is Kengai
and not Repni. The historicel " $n$ has boen absorbed into the root.

The present root moni vas generated froe / $/ \mathrm{n}$ -
Bani/ through Ganda law. This rule is still operating in theae dialects e.g. gan- 'tell tale' cbances to ganj
'stories'( $n-$ gan-) / The singualr for this is 'rogan 'story' or Kaganz 'a short story'. Unlike Euni the root for this morpheae has been retained as san-.

In syachronic gramaars Gauda law affects $/ \mathrm{r} /$ and 疾i only. For other sounde this rule is not operative. As far as * roots are coacorned the rule is dorment bat its effects can still se seed. Note for axample, that the verb for 'see' dini. To mal ve can add other profixes e.g. impni 'oig papils'.

It is obvious from the above examples that restructuring has taken place in some of the roots. In such cases no amount of abstraction can be used to generate the synchronic forse from the proto-roots. Any such abstractions cannot be said to be a part of the synchronic gramars of these dialecte.

### 2.2.5 Morphologioal Motathesia.

Motathesie is a common concept in many linguistic
Iiteratures e.g. Choncky and Balle (1968) Sohane (1973)
-tc. N1 the availeble literatere concentrates on phonologioal motathonia. Mobody, to my knowledge, has discreoed any form of netathesif that is conditionod by the norphologicel status of the sounde involved.

In thi section we shall discusa sone Eetathecis that 1: motivated bj the morphological status of a given sonnd. Before getting into the discussions let it be clear that the distinction betweon phonological and worphological atathesis is that the former should have no exceotion While the latter bas some exceptions. In a phonological Eetathesis a given sequence of sounds is interchanged in all cases. In a morphological motathesis only the sound with morphological status is moved. An identical sound which has no morphological otatus is not moved.

Tine difference between these two types of aetatheeres 1s reilected in rules 34 and 40 of this section. The first of these two rules shovs a phonologically notivated metathesis while the second shows a morphologically sotirated aetathesis. In order to understand the differences between the two wo shall ifat discuss phonological eetathesis than $g^{\circ}$ to morphological metathesis in the last part of this section.

Many linguists have discussed or formalized phonological motathesis. The discussions that one finds in most books are liaited. Thej siaply atate which sounde vill change irow one order to another without going into the motivations

```
behiad the ohanges. A typical example of the types of
statenents that one finds in many books is found in Scbane
(1973) Schane discusses metathesis and gives the folloving
statement on Hanunoo metathesis,
'In Hanunoo, the cluster glatial stop and consonani beconies consonant and glotial stup when internal...that is between vowels.'
```

Schane formalizes the Hanunoo rule as in 3 i
34. $v\left[\begin{array}{l}\text {-cons. } \\ \text { +stop }\end{array}\right] \mathrm{C} \quad \mathrm{V} \Rightarrow 1324$
$\begin{array}{llll}1 & 1 & 2 & 3\end{array}$

Rules like this are found in many books. Many of
ther do not have any formalisas like rule 34. These rules do not talk about the underlying motivatione for this common concept. The constant absence of any discuscione on what motivates the process raises eerious doubte as to whother our linguistic theories have achieved the deaired explanatory adequacy.

It may be that this absence of any disounsioas about the motivations of motathesis is due to many and varying types of netathesis that are found in difforent languages. This ought not to be good reason for not investigating such gotivations because we have both linguistic universale and language specific phenonena in our linguistic theories. Oae should expect to have soee discussions as to what gotivates a given metathosis in a given language. As we chall see later differeat languages mas bave different
constrainte on sound clustering. These conatraints may be the carse of many types of motathesis.

In the last fev yoars sune lingulste have tried to explain the motivations for wotathesis. Among those who have discussed this process are Hooper (1973) Bailey (1970) and Vennemann (personal commanication). In our discussions Vennemann referred to Baily's article (which I have not sean) which he says aakea a claim that where stopa are involved in motathesis, the apical ones cone last. Vonnemann gave the following examples to support the clains-

35a. Greok:

$$
\begin{array}{lll}
/ t k / \rightarrow k t & \bullet t i-t o k o>t i t k o & \text { tikto } \\
/ t p / \rightarrow p t & \bullet k^{w} \text { id-pe }>t i t p e & \text { tipte } \\
/ n m / \rightarrow n & \cdot \text { nesodme }> & \text { mosomn }
\end{array}
$$

## 350. Bebrev:

| $/ t \pm / \rightarrow a t$ | -hit-mader | histader | - (the) | got organisod." |
| :---: | :---: | :---: | :---: | :---: |
|  | hit-saret | mistaref | - (he) | joined.' |
| $t 8 \rightarrow 8 t$ | hit-baper | nistaper | - (he) | improved.' |

Uith these examples Venneman claies that the outpit ol netathesic is easior to produce than the input. Tho hypothesis is that the role of metathesis is sluster simplification. Fror the output it is clear that syllabloa ending in certain stops are disalloved whil those onding In continmants are preferred. To us this claí seeme to be woll motivated.

For Hooper metathesis may result from pressere to make oyllable initial poaitions stronger than syllable fiaal positions. In some Languages e.g. Spanish, syllable structure constraints rule out any conconantal clustors of the type $C_{1} \& C_{2}$ if 1 ie stronger than 2 (c). Hooper 1973 obp. 9). The oxamples given to oupport this claia Include:-
36. /reara/ rera he vill cone. /ponrá/ pormá be will pent.

According to Hooper netatheais arises beoause /r/ is weaker than $/ a /$ and cannot therefore oocur in byllable initial positions after $/ \mathrm{n} /$ which is stroger than it. If such typee of structures were to be allowed the results vould be strong syllahle final poeitions but weak syllable initial positions. Such structures are not allowed in the surface foras of Spanish. Note that some other dialects of Spanish use opentheais to achieve the same objoctive. Is such dialects the above fomas will surface as[vendra] and [pondra] respectively. The latter examples leave no doubt about syllable structure constraints.

In ail the above examples it is posaible to see the motivations of each case of metathesis. Ao stated earlier on, these motivations need not fit in ing gistic univereals. They may be limited to one particular language which uses a lindted set of constraints on the clustering of sounds.

In S. Mt. Xenya we have a number of caces that show eridence of metathesis. These include ajlable owitching and morphological metathesie. This morphological metathesis moves a particular norpheae to partioular position. Before going into morphological metathesic let us have a look at phonological metathesis. The most comon examples of phonological metathesis ares-
37. (1) /Eigana/ [ Kinagana]/ [Gigana] 'how many cl.9'. (ii)/Lanaka/ [ cadaka] / [danaka] 'rule over.' (1i1)/taguna/ [tenuka] / [taguna] 'chev'. /nodamaki/[momadaki]/ [modamaki]'ruler.'

Examples 37 (i) and (ii) are very common in soae people's speech. These are only heard in Northern and Southarn dialecte. Examp-e 37 (ii) is more common in many parts of Northern dialect than anywere elee. In such parte we have[damaka/ madaka]'rule' and [modrmaki/ momadaki] 'king'. These are common but sporadic in their occurences. Example 4 (iii) is dialectal in that eastern dialects have [taguna] while vestern dialecte have [tanuka]

As the examples in 37 reveal where metathesis has occured the veler consonante have been placed in the last cyllable. . Vafortunately our data is so liaited that we cannot justifiably write a general rule for three words only. The intereating thing that we chould notels that Whon two anterior (1.e.[-back]) consonants are separated

#### Abstract

by a relar conconant the velar sound is avitohod to the lat sjllable. Mis awitohing leade to etructmre in which the two anterior sounds are in adjecent eyllables. The output of the rule can be sald to be oaser, to produce, than the imput. This output is easy because sonnde produoed by a given part of the tongue are grouped together.

The sorphological metathesis referred to earlier involves the movement of a historically cansitive e $\{1\}$ to the last sylable of the surface Etmcture. This nistorically causitipe\{i\} need not, today, express a cansitive idea. To exempilfy this rule we have the following exameles:-

| 38a-roots | Cl0s8 | Roots+perf. tenes | G1088 |
| :---: | :---: | :---: | :---: |
| un- | 'break' | en+et [ [unet E] | 'has |
| 2h- | 'tie' | Jh+otc [Jhetc] | 'has |
| rakar- | 'be angry' | rakar+ete rakaret | 'has | kan- 'ailk' kantetc[kamete] 'bac milled. =

38b. ari- 'talk' aritetह[aretik] 'mas talked'
Bari- 'look for' Sari+etc[Baretic] 'has looked Sor' ati- oplit ati+at\&[atetic] 'has eplit'
guti- pull eudi+etc[gusetic] 'haE pulled'.

| 38c. roote | Glose Rootstperf. tense | G1080 |
| :---: | :---: | :---: |
| 81- | 'trouble' si+ote [siete] | 'has troubled' |
| huria | 'rhinoceros' Muritet [hurlete] | 'has become a |
| - | 7 | rhinoceros'. |
| jgatia | 'lion' ygatitetr [ggatietc $]$ | has become a |
|  |  | lion'. |

Fron the above examples $i t i s$ quite clear that we have two types of $/ 1 / \mathrm{B}$. There are those $/ 1 / \mathrm{B}$ that wove to the last syllable e.g. 38b and there are those $/ 1 / \mathrm{s}$ that do not e.g. 38c. Por these $/ 1 / \mathrm{s}$ that move we have the following rule:-

396 1+etを $\rightarrow$ 2314.
1234

Some people might want to argue that the solution to this problea lies in the fanctions of the verb. For suoh people all the verbe that attract this movemen vould be transitive verbs. All the verbs that do not have this /i/ movement vould be olaesified as intransitive verbe. This solution will face aumber of problens. One of the problems is that not all the verbs that have/1/ movenent are transitive in meaning. A verb like [arjá]'talk' will hava [aretic] 'has talked' </ari-ete/. One would find it bard to drav a clear line between transitive and intransitive if meaning was to be the prime factor.

The fact that sote verbs that end in $/ 1 /$ do not switch this sound to the last sydable, wile otharn do, ceans that this rule is not phonologically wotiveted. If it was phonologically motivated it would have mo exceptions. The distinction between thase two types of /i/is morphological. The rule is, therefore, motivated by the murphology of these dialects.

The /i/ movewent rule is dependent on the sorphological statue of the noving /i/. This /1/is historicully froma causitive : $\{1\}$. The position of this morphere was, and is atill, liaited to the last syllable of the surface structure. This geans that the morpholical $\{i\}$ has to be placed before the final vowel. If this rule was to be formalzed it vould be as 40.

## 40. Caustivev $[1] /-v \%$.

Tbis rule has no phonological motivation.

## An interesting point that should be noted is

that the moving /i/s are nore than the unmoving /i,'s. Very for verbs seen to ond in this unmoving /i/. It is for this reason that sowe verbs have been made out of rouns (cfe 38c). The actual number of unmoving /is's is not poisible to got because not all verbs of the dialeces are liated.

The sulution given above means that all the verbs with the moving $/ i / 0$ will be wariked with a diacritiv feature (+cansitivo). This fegture will triger the
novenent of the underlying /i/ to the last syllable. The verbs without this diacritic foature will not meet the atracteral deacription of the caucitive movenent rule (on rale). They will therefore not have their $/ 1 / \mathrm{e}$ moved to the laat eyllable.

This aolution weans that jounger language learmors enet learn the distiaotion between the two types of $/ \mathrm{s} / \mathrm{s}$. Any aislearning of these two sounds would reault into oither rule loss or rule generalization on phonological grounds. Oatil this happens the rale must be treated ac a morphological one.

Ao already indicated the gauclive movenont rule is an altermative title to morphological netatheale. Any of these two titlea will be good enough to describe the procese. Whatever the title one uses the process readas morphological.
2.2.6 Analogical extensions.

Traditionally analogy was seen as an agent that rescued paradigatic regularity from irregularities created by sound lawe. For this group of Iinguists owphasis was placed or what they called proportional analogy. For the genorative gramearians this tem was overshadowed by rule generalization. Some generative grammarians like King (1969) have even dienissed the concept as unnecessary. For this group rule generalization is onough.

In this section we shall examine a number of rules and examples so as to find out if this term is necessary in our theory. We shall try to find out the best way of accounting for a number of changes that occur in our region of study. The first of the rules to be discussed is nasal deletion that we discussed in 3.2.2. Remember that wo concluded that this rule has had three stages which may be set as follows:41

$$
\left[\begin{array}{l}
c \rightarrow n \\
+n a s a l]
\end{array}\right]\left[\begin{array}{l}
-\operatorname{con} \theta \\
-\operatorname{oc} \cdot \\
-h i g h
\end{array}\right]
$$

42. $\left.\begin{array}{c}C \rightarrow \theta \\ {[+ \text { nasal }]}\end{array}\right]\left[\begin{array}{l}{\left[\begin{array}{l}\text {-cons. } \\ - \text { or. } \\ - \text { high }\end{array}\right]} \\ {\left[\begin{array}{l}\text { +cons. } \\ + \text { voice } \\ + \text { cor } \\ -s t o p\end{array}\right]}\end{array}\right]$
43. $\mathrm{C} \longrightarrow \mathrm{F} \quad \mathrm{H}-\mathrm{C}$
$[$ nasal $] \quad[$ troice $]$

We have no doubts that the above three rules existed
in Western dialects of our study. We also have no doubt that they occured in the above order. 111 these facts are revealed in 3.2.2.

Given the above rules one may want te account for the present day phenomenon by rule generalization or by
proportional analogy. For theec changee rale genoralization would be enough and there is ao noed for an appeal to analocy. The generative gramariane who dienies analogy vould argue that this is a phonologioal procese which is phozetically notivated and therefore needs no other justifications. The phometio motivations are that no voiced cluetere are needed in initial ayllables.

The second change to be discussed in relation to analogy involves the oxtension of the first person aingular marker, In negative constructions only, to both second and third persons. In order to understand this rule let ne compare examples given in 44 and those given in 450 When comparing the two sets we should take note of the differences in their underlying representation:-

| 44. (1) | $/ \mathrm{n}-\mathrm{ti}-\mathrm{ra-ds} /$ | ndiradie | 'I am not going'. |
| :---: | :---: | :---: | :---: |
| (11) | /n-t1-80-Bana/ | ndigotama | 'I an not to tante'. |
| (111) | /n-ti-na-rea/ | ndinarea | 'I did not eat.' |
| 45 (1) | /o-ti-ra-dio/ | ndoradie | 'Iou are not going'. |
| (11) | /a-ti-ra-die/ | ndaradie | 'He is mot going'. |
| (111) | /0-t1-80-Lama/ | ndogatama | ' Iou are not to taste'. |
| (iv) | /a-ti-80-Cana/ | adagotama | 'He is not to taste." |
| (t) | 1/0-ti-na-rea/ | ndonarea | 'You did not eat.' |
| ( $\nabla_{1}$ ) | /a-ti-na-rea/ | ndanarea | 'He did not eat.' |

A comparison between underlying and surface forms
shows that surface forme are more similar than their underlying
counterparts. We note that all the surface forms begin with nd- which mut be accounted for in our grammar. Note further that unlike in thwhere subject marker comes 45 before -ti- all surface forms in show the subject marker as occurring after nd- which $2 e$ rather strange, if we assume that this is derived from -ilo.

In order to explain how we get the surface forme in 45 we have two choices. One of then will be analogical extension of -nd- as a singular marker and not a marker for the first person singular only. The second alternative will involve metathesis, rowel deletion and a epenthesis.

By using the second alternative we shall have the following rules:-

48. $\varnothing \longrightarrow[n] \quad \mathrm{H}-\mathrm{C}$

$$
\left[\begin{array}{l}
+ \text { cor } \\
+ \text { stop } \\
- \text { voice }
\end{array}\right]
$$

On the basis of the generation of other diphthongs in the dialects rule 46 then be as it is. It should not be
allowed to generate toil or tai because rising diphthongs are not allowed on the surface. The generation of rising diphthongs would make $[1]$ deletion in 47 unmotivated. Since rule 46 has generated falling diphthongs rule 47 is motivated by the constraints on she generation, of diphthongs.

Rule 4 is the most suspicions of all the three rules. As we noted earlier the Western dialects have initial nasal deletion. We also noted that the initial nasal wore Eorphophoneaic. They were not generated for the sake of their generation. Rule $u 8$ is unmotivated in that it is neither morphegically nor phonetically motivated. For these reasons we must reject it as another trick to cover up the weakness of our linguistic theory.

The first alternative takes nd generated from $/ n+t /$ as the origin of the present day situation. Since this form was first generated as the lat person singular marker the speakers extended it to all three persons. The singular marker was generalized as - nd- with the person marked by the vowel i.e. 1,0 , and a for first second and third persons respectively.

This approach does not need to generate [nd] from $/ \nabla-t i /$ because the motivation of this form is not phonetic. The motivation if conceptual. According to this approach
a claim is being made that all the three persons were conceptually grouped together. They were all singulars and therefore needed or should have a single form to mark that
singularncss.

The analogical extensions discussed here are rotivated by grammar 3iaplification. This type of ainplification differs froa other types of eiaplifications in fore only otherwise they all achiere siapler grammers. Rule gonoralisation as givon in King (1969) and analogical extonaions have the same and resulte and our theory should be able to show this. In this partioular oase rule generalization vill not do because there are no taderiying notivations. We must uee analogy in order to account for thia type of granar oimplificetion.

These extensions have gone to all the dialecte al Southem Mt. Eenya dialecta but are fully generalised ia Nestern dialects only. In these Western dialects wo bave no surface forms of the type VCV, which are found in Bastern dialects. Fastern dialecta use VCV in all ampatic expressions. For clarification of the dialectal differences coupare thees surface formesin $4 \%$.

There are eany other examples that one can give to show the differences. These Eastern examples are used when enphasis 10 neoded. This is psually so when the bearer seeme not to accept the lact e.8. for 44 a (1) the speaker may sey that a givan person 1 s called $x$. The hearer may suggeet different name which akes the speaker come up with an emphatic denial of the later name. If no emphasis If needed or used the above forme will be realised as in soe
48. a) Ki-Gichuer

## G108:

'He is not ended. 1 It 18 not called
'It is not to eat"
'he 18 not to so'
'he is not called'.

- He is not called.
'It is not called'.
'He is not to got.
Whother one mants to argue that the Eastern dialeots have borroued these forme or not is not important to ens diecuseion. The important thing is that amalogical lovelling has taken place in all the dialecte but at differest ratea. In Western dialecte wo have so surface form that rotain a direct link with the underlying fome. The erucial questios would be whether any generative phonologist would have a mule that changes $N+t /$ into [nd-]. We hope no one will auggent such kind of rule for such would be unootivated in any theory. The only way to account for this is by appealing to asalogy.
In conclusion it should be realized that different dialecte have differeat rates of anological levolling. The eastern dialects of this region are slower than their western counterparts. Wis to $u$ is an important feature of dialectalogy.

## Footnotes:

1. re 'Verb to be' has varied meaninge depending on the contezt. These varied aeaninge ares-
2. he/she 1s, has, was.
3. he/she 1s in possession of
4. ho/she is, was at.
5. In 3.1 .3 we argued that mb- was generated from /nB/ by a morrhological rule. Wo no longer have /B/ as a phonero in K1-Eabu.
6. Enpi 'pupils' (of eyes) must be generated froa / /aB/ and not iron $/ n-3 n i /$. The change from $/ \mathrm{nB}$ oni/ $>$ noni in generated through Ganda law but no change fron /n-jni/ to moni would ever take place in tbese dialects. Such a change would have no phonological notivation.

## CHAPTER THRES

Conparative Phonology and Diachronic Changes.
3.0 In this chapter we shall deal with diachronic sound shifte that hare occured in S. Mt. Konga. Tho main objective will be to find out to what extent these dislects differ or agree in sound structure. The findinges will reveal how close the genetic relationship betwoen those dialects is. We shall also be interested to find out which rules have operated in each dialect in order to have the preseat day sound structures.

The chapter will consist of three parta. The firat part will deal with consonante and the rules affecting them. The second part will discuss the vowels and any rules that affect then. The final part will doal with tome and tone patterne found im this region. In all threo parte ve ohall discuss diachronic developaents that established the sychrovic differences. Synchronic rules will only be coneidered where they show some light on historical developments.

As atated elsewhere in this study, Guthrie has classified the whole of S. Mt. Kenja as one language. He calls this language 'Kikugu' and labels it $\operatorname{s51.}$ ' He mentions Imbu and the says that it is similar to E51. The only difference that be cites is " ${ }^{\prime \prime} \mathrm{P}>\mathrm{BH}^{\prime \prime}{ }^{2}$ Wo interprete this to mean that in all other respects ©obu is like 551 , according to Guthrie. Siace he does not rention any other
dialect except 'Eabu' and 'Kikuyu' ve shall assume that for hin no other dielecte exist in the region.

Quthrie is not wrone but his assumptione of wat the comparative nethod ind 'Internal heconetruction' can do were wrong. In his discussion of the viability of comparative nethod he had this to say:-

ITHere is no need for use to discuss bere the implications or the merits of this technique. eince the likelihood of its being able to produce results is so renotell (Guthrie 1948:20).

This statement was meant to claim that there is no possibility of showine different types of relationchips i.e. wo cannot prove that a proto-language A produced B and C and that $C$ later produced $D$ and $E$. Diagramaticelly me denied the following reaultes-

For hin the conparative method could only produce 'useful deductions' for the reconstruction of a common general ancestur i.e. one proto-language. The method was incapable of showing any intermediate stages. He, therefore, concludes his book by sajing:-

```
"Any who may have looked in vain for some
indication of the closeness of the relationship
betveen one group and another should bear is
|ind that there 1s no standard against whiob to
measure such relationship. It was, therefore,
necessary to avaold expressing any ideas on this
subject, since they could not have trully
objective basis, (Guthrie 1948:73)".
```

Guthrie' ${ }^{\text {e }}$ defeatist attitude should not be accepted in our theory of sound change. The lact that one group of dialects or languages may have certain changea while other groups have other ohanges seans that we can reconstruct the most recent mother languge of each group. The comon changes to the two dilserent group will. in tern help us to reconetruct the rext common mother language. Note that Guthrie's objection to the possibility of this aethod being used to establish intermediate stages is not based on Iinguistic information but on lack of. 'historical records."

For Guthrie the reconetruction of Proto-Gemenic and Proto-Romance as intemediat stages in Indo-European languages could saly be posuitle bacaube of the aveilability of 'historical recorde.' Such a claim sevme atrange becanee there are certain cound changes tbat are linited to oach of these groups which could be used to establish a proto-language for each group.

The assumption of the witer is that the comparative

Mothod and Internal Reconetruction have more utility than Guthrie was roady to accept. This very claia has beon aade by Hinaobusch $(1973)^{3}$ who argues that we can infact
establish closer relationships by using the same weinods that Guthrie dismiseed. With these few renarke we now turn to comparative phonology of S. Mt. Kenye.

### 3.1.1 The Consonante.

Looking at the sounde found in these dialeots one can -asily reconstruct the folloving sounds as the sounds of the once common language of $S$. Mt. Kenya, hence ProtoSouthern Mt. Kenya.

Each of the dialects of this regions has deviated from the above sound structure in a number of wajs. On individual dialect basis we have the following analyais:-

|  | $\pm$ | $B / B$ | k |
| :---: | :---: | :---: | :---: |
| $\checkmark$ | 4 |  | 8 |
| Mb | nd | - $\dagger$ | ng |
| - | n | $\rho$ | 5 |

In Ki-Mbeert these sounds have come into being through the following changes:-

```
\(/ t /<\cdot t\)
\(/ 8 /<\cdot\) te and \(\cdot B /-1 a(c f .2 .2)\)
1*/ < k
\(/ \nabla /<\cdot p\) and some 150 - \(B\)
\(\mathbb{N}<*(n)\) ts and some frow t (mainly cl. 10).
\(181<\cdot 8\)
/ab/ < \(n\) n and soon -mb- (1.e. Medial)
\(/\) ad/ <*ry nt and -nd- (ie. medial position)
\(/ \mathrm{ng} /\) <ag; \({ }^{\text {nf }}\) and -ag- (1.e. medial position)
\(|r|<r\)
/a/ <"m and some from in through Ganda law.
\(\mid n /<\bullet n\)
```

```
\(/ \mathrm{g} /<\mathrm{n} /\) - velars which were later deleted by Ganda
law.
\(/ w /<0\) followed by a or こ. There may have been sow
    - /wis that were earlier developments of tho
        saэะ rule.
\(/ \mathrm{j} /<\cdot 1\), e followed by back vowels. There may
        have been earlier fores of this rule at the
        proto-stage.
```

The two dialects have almost identical sound atructures and will therefore be discussed as a single group. The
major differences are discussed and exemplified in chapter 2．In sound structure the only difference between the two if that Ki－Eabu has／$/ \mathrm{L} /$ or／B／while Ki－Mbeere has uniform ／8／．In Ebb sone people have／e／wile others have／／／ In most cases the two sounds villi fluctuate freely without creating meaning differences．

3．1．3 Ki－Gichngu－Ki－Ndie．
These two dialects have identical sound structures．
The major differences are in morpholexical differences that have been show throughout chapter 2．Being identical in sound etractares means that they should be discussed as a single group．The same was done for Ki－Enbu and Ki－Mbeere． 3．$t$ te $k$

| B | 1 |  | g |
| :--- | :--- | :--- | :--- |

\end{aligned}
$$

### 3.1.5 Northern dialect and Southern dialect:

These two dialects are almost identical to Mathira.
The only differences that separate them from Kl-Mathira is the following change:-

$$
/ d /(n) t a
$$

The difference between Northern and Southern dialect
is that while the Northern dialect agrees With Kl-Mathire
in having $/ f /<\bullet B$ Southern dialect has $/ B /<-\mathrm{B}$. In all other changes the two dialects agree with Ki-Mathira.

### 3.2.1 The historical rules:

From the above comparisons one finds a clear grouping of the seven dialects into three wain groups. These are the Ki-Enbu - Ki-Mbeere group, the Ki-Gichugu - Ki-Ndie

#### Abstract

group and the Western group that consiste of Ki-Mathira, Northern and Southern dialectb. In the followire fow pages we shall discuss the historical rules and possible lines of changos that might have taken place in ach or the three groups or in individual dialecto. Again, the diecussions will be, mainly, limited to historical changes.

3.2.2 K1-Embu - Ki-Mbeere group:

As indicated above ( 3,2 d the voiceleas bilabisl stop $/{ }^{\circ} \mathrm{p} /$ has shifted to a labiodental position and, aleo, changed from a etop to voiced fricative. It ras also indicated that there occered a merger of ${ }^{\circ} P$ and ${ }^{\circ} B$ in this group. The morger did not affect all the casee of 'B beeame sone of thea were lost belore p changed into /V/. This -arger is a vory interesting change especially whou one compares the differences botweon this gromp and Kl-aichugu - Ki-Ndiagroup (3. Y.3). Let ue flrat coneider the elfift fron * to $/ \mathrm{F} /$.

Hinnebusch (personal communication) argues that the, 'ehift fron ep to $V$ is probably part of the areal phenomenon affecting most Bantu languages in which $\langle P\rangle * \Phi\rangle V\rangle \overline{\$}$ (betweon rowels) or $* P>\Phi\rangle \mathrm{A}>$ D. In Hinnebusch $(1973)^{4}$ he callethis change P- lenition. Hinnobueca did not consider the change of ${ }^{\circ} B$ to $V$ probably because his interests were in Kenyan Coastal languages where this change did not take place. The procese of change offered by Prof. Hinnebusch is common in Bantu langrages and cannot therefore be disputed.

The fact that a procese has occured in one language or group of languages does not, however, inply that it occured in another. As such ve cannot clain that the above trend of P-lenition took place in S . Mt. Kenya Without giving enough proof that it actually followed those lines. In this region there is no ovidence to suggest that or has erer existed. All the available facts show that this sound (i.e. P P) has changed into $V, B$ and h at some stage in its lenition. We shall come back to this sound shortly.

In a historical order ${ }^{\bullet} P>V$ auct be placed aftor - $B>$ in most environmente except when after nasals. By eajing after nasals one aight want to make this statenent clearer by altoring it to state that $B$ was preserved only in norphemes thet generated Mb - from "nB thus creating an alternation between Mb and B in the same root. This is wore revealing than baying; 'after nasalc.' These morphophonemic alternations occured in clase 9/10 morphemes, as exemplified belcu (see map 3):-
5.

|  | Proto-10r | G1085 |
| :---: | :---: | :---: |
| Hbalc | $<\mathrm{n}-\mathrm{BqEE}$ | eront(s) |
| Mboli | $<\mathrm{n}-\mathrm{Bori}$ | goat(s) |
| Mbura | $<\mathrm{n}-\mathrm{Bu} \mathrm{ra}^{\text {a }}$ | rain(s) |
| MbEgo | < $n-B \varepsilon_{80}$ | ceod (s) |
| Mbode | < n-Betse | unripe |
| Mbaara | <n-Baera | war(s) |

The above examples differ from these of 6 in that ozemples in 6 have lost the $/ B / B$ of the provo forms. The onvironeonte in which this sound was lost are quite clear:-

To generate the above forms from tho provo language we have rule $7(\operatorname{man} 3)$.

The interpretation of rule? is such that those proto "Ba that came after nasals wore not initial and were therefore not subject to rule?

As stated above rule 7 operated long before -p-lenition odoured. In this group of dialects, foe. Ki-Mbeere and Ki-Enbu, ${ }^{\circ} P$ is most likely to have shifted as shown in 8.
8. $\cdot P>V \quad N-V$.

The above rule was later generalised to all environments thus causing restructuring of ${ }^{\circ} \mathrm{P}$ to $/ \mathrm{N} / \mathrm{A}$ After restructuring some
initial occurences of $/ \mathbb{V}$ wore doleted thus generatiae such form as "avá from 'Papa 'here'.

The above change occured in both Ki-Mbeere and KI-Embu but the present day surface form have different dialectal variations. As will be seon in this section and fron the examplee below Ki-Mbeere merged proto sounds $B$ and *P into $N /$ but merged ${ }^{*} n B$ and ${ }^{n P}$ into $m b$. Ki-bimbu did not $\operatorname{serge~the~two~sounds~completely,~in~the~latter~}$ onvironment. This is shown below:-

| Mi-Mbeere | Ki-Embu | Proto | Glose |
| :---: | :---: | :---: | :---: |
| Mbiti | 3viti | piti | $\underset{\text { hja }}{\text { én }}$ |
| -tis | mbis 3 | pig | kidrey |
|  |  | $p \in p$ | cold |
| mbu:nda | yrusinda | punda | donkey |
| Mbalika | Mralika | parika | abe goat. |
| Mbal | Mvelc | pare | I seratch |
| Mbir | -biro | Biro | soot |
| -bold | -boll | Bori | gont. |

Fron these exanples we zote that K1-Fbe had kopt a
 poople lont thoir wemory of what roots belonged to what sound. The loes of thic dictinction resulted into some confusion which led to sone ep roote surfacing es ${ }^{\circ}$ B rootewhile some "B roots were anrfaced as "P roots. Despite these confusions we can still write rules to account for
these differences. The rules will be as show in 10 and 11.
10. ${ }_{\bullet}^{\circ} \mathrm{P}$
11. $\cdot P>/ N / / H-i V-V$ (Mbeere and Embus).

These two rules are adequate to account for the difference e between Mbeere and Erbu.

Another change that occurs between Ki-Mbeere and Ki-Rabu is the occurence of /B/ only in Ki-Mbeere but /s/ and $/ \mathrm{B} /$ in Embu. In Embus scar speakers have $/ E /$ as the only sound to correspond to K1-Mbeere's /B/. Other speakers have /e/ corresponding to Ki-Mbeere/s/. These two varieties of -ts do not seem to follow clear dialect boundaries in Ki-Embu. This masses it hard for the researcher to decide which one to list as the Ki-Embn variety.

The impressionistic picture that one tends to get is that southern and eastern Ki-Inbu have /a/ while northern Mi-Eabu tends to have /8/. In each of these regions ore gets pockets of speakers, with either of the two varieties. As we could not, non-arbitrarlly, choose one of then we have listed both as Ki-smbu reflexes of te.

The palatal and the velar nasals ie. $/ \mathrm{F} /$ and /I/ are found in all the dialects of our study. These two sounds nay have been part of the sound structure of the proto
language of this region. This fact cannot be established beyond reasozable doubts. They way have been allophones of - which were later phodemicised by certain changes.

One of the possible changes that may have lod to the present phoneses is the change of the proto form 'ni, which was both first porson singular warker and clase 9/10 prefix, into /pi/ when the roots began with vowels. This vould suggest that $/ \mathrm{ni}+\mathrm{a} /$ would change into $/ \mathrm{pia} /$. This claín is supported by structures such as ainc <eni=1n=c 'May I sing,' ningers < ni-inger -E 'May I enter,'

In the dialects of our study we have foras euch as nismé 'finish', nini 'mall' nùngá 'anoll' (vorb) etc. Such forme as these indicate that there is mo palatalisation bofore high vowels. The change from "n to $/ N$ mot have cone from *miV.

Assualing the above change began by changiag ent lato תi when roota began with vovels it is the cace that this rule wes generalised to affect all morphenees of clase 10 evon after al was redeced to n . This explains why vo amy, aboli me:nge 'many goats' < $/ \rho^{\circ} n+0 g g e /$ mboll mber a 'good goats' // $n-B$ cga/ instond of "nivese, which would be the present day form after ${ }^{-} B>V$ in these two dialecte.

As for $M /$ it is the case that most of the present day surface forms are historically derived from in through

Ganda law. The following few examples will illustrate:-

These examples need rules 13 and 14 to generate the surface format:
13. "ny /iv- velars
14. $\mathrm{c} \rightarrow \phi / /_{\Gamma}^{c}$

$$
\left[\begin{array}{l}
\text {-stop } \\
\text { point }
\end{array}\right]\left[\begin{array}{c}
C \\
\text { nasal } \\
\text { point }
\end{array}\right]=V\left[\begin{array}{c}
C \\
\text { +nasal }]
\end{array}\right.
$$

fine 13 assimilates $n$ into the velar position of the voiced velar fricative while rule 14 deletes the latter.

It right be questioned as to whether there, actually, exists a velar fricative in the underlying forms of tho examples in 12. To answer such questions one should fut that roots into test. The test is to place these rents 1 is
 Kazan Kane ni etc. This test proves that there exists a velar frioative that leads to the change. The sane thing happens to those $/ M / E$ that are derived pron $/ 8+B / \bullet \cdot B$. and 'eyepupila!

On the surface there may be no connection between young language learners need not
/J /ana /8/ 2.e日 learn the underlying forme. They, mont likely, learn the surface forme a class of morphemes. It is unlikely that children will associate ap me with gu abe. In fact young ohild. said that the calf should be "Kamanbr. Wen I asked hin why it vas not Kano bb e he could not answer.

From rules 13 and 14 we have got large number of surface forme with $/ \mathrm{g} /$ that historically come iron ". in Whether this sound was phoneme the provo language or not is not important to the claim that Ganda law has increased the occurence of $/ \mathrm{g} /$ in the dialects of S . Mt. Kenya.

In concluding this section let us consider the status of $/ w /$ and $/ \mathrm{f} /$. These two sound e can be said to be mainly derived from vowels. Even today most of their surface realsations are allophowic to their respective vowel sources. $[\mathrm{W}]$ comes from / / / while [j] comes /i/and/e/e The rules that generate these allophones are exemplified below:-

These gilding rules are so clear that they need no further comments.

What is of interest is the fact that even the present daj phonenic $\mathrm{N} / \mathrm{s}$ and $/ \mathrm{J} / \mathrm{s}$ may have reaulted from earlier gliding. Unfortunately it is not posaible to give an example in which $/ \mathrm{J} /$ can be eaid to be phonemic. The only available examples are those of $\mathrm{N} /$. These are given below:-
16. jgwaze
mokwadi
abwe
rwage mosquitoes.
Mbwe
potatoes. a type of a bird. grey hair. fox.

It is most likely that the above /W/E are derived frow \%a/ ot ©/ua/. There is no way to test whether or not the glide and the preceeding stop are one or two sounds. It is
likely that the tio are separate i.e. hiotorically. The medial clusters are always together but the initial ozes are separable.
3.2.3 Ki-Gichugu - Ki-Ndia.

In these two dialects p-lenition took a different route from that of Ki-Mbeere - Ki-Eabu group. Unlike in KiMbeere - Ki-Eabu group where $P$ and eB Eerged into / $/$ / thie group nerged the tvo sounds into $/ B /$. Another iaportant difference betweon this group and Ki-Mbeere - Ki-Enbe group is that in this latter group the two sounde did not shift to a third value but have joined into one of the two proto sounde.

It vas noted earlier, that in Ki-Mbeere and Ki-Rabu
 The sane thing happened in Ki-Gichagu and Ki-Mdie. The losses are exemplified below:-

From examples in 17 it is clear that rule 7 Las operated In these two dialects. The only question that we need to ask ourselves is whether rule 7 is general enough to delete both "p and "B in initial and intervocalic positions. It sens that this rule is not general enough because it lists - B as the sound to be deleted. To avoid this inadequacy wo have to reformulate rule 7 as rule 18.
18. $\cdot \mathrm{C}>0 \quad \mathrm{H}=\mathrm{V}$ - C

$$
\left[\begin{array}{c}
\text { +Bilabial } \\
\text { +continuant }
\end{array}\right]
$$

Rel. 18 deleted any continuant labial consonant whether voiced or pot if it occured in initial or in intervocalic environments. The rule is general enough to account for the changes that occured in these four dialects.

Rule. 18 first operated on * $B$ and got rid of it except
in alternating morphemes (i.e. "nb / B) After the operation of this rule p-lenition occured. The first change was, probably, the voicing of $\cdot / \mathbb{P} /$ into $/ \mathrm{b} /$ then cane the change from stop to fricative, foe. "Pb /B/. At this stage rule 18 operated and deleted a umber of $/ B / \mathrm{s}$ that had come frow $\mathrm{P}^{\mathrm{P}}$.

The change through voicing first is not strange especially when we note that these dialects like most other Bantu languages could easily generate bb from $n+* P$. A rule like this one could merge the two sounds into one in this particular environment, i.e. rule* 10 After the application of rule 10 restructuring occurred thus changing ${ }^{\circ} P$ to "b. This of change vas followed by the change of ${ }^{\circ} \mathrm{b}$ to $/ B /$ thus completing the change. Historically these changes are shown in rule 19.
19. $\cdot \mathrm{P}>\mathrm{Bb} / \mathrm{b}>0 / \mathrm{b} />\mathrm{B} / \mathrm{Bb}>\mathrm{B} /$ 。

The claim that ${ }^{\circ} \mathrm{P}$ could only change to be for nasals is ampported by example in 20 which show the merger of ${ }^{\prime}$ P and ${ }^{\text {Bi- }}$

An interesting fact to note is that no intervocalic

* B or "b listed by both Meinhof and Guthrio can be seen today in any of the dialects discussed so far. The present day intevocalic $N /$ and $X$, found in these two groups of dialects are all derived from ${ }^{\circ}$ P.

The above discussions and rules have proved that in Ki-Gichugu and Ki-Ndie there are no reflexies of ep to be found on the surface. In these two dialecte * P can only be traced trhough $/ B /$. This is a true generalization for all native speakers of these two dialects. There are, however, some Ndia people who have some $/ \mathrm{h} / \mathrm{s} /$ There are the people who have borrowed this sound from western dialects.

The borrowing of $\mathrm{M} /$ into Ki-Ndia is limited to the young and the educated people who have come into contact with the written language, Since the written Innguage is based on the two main western dialects those who have learned to read and write have known the existence of $/ \mathrm{h} /$. Furthor ovidence of the borrowing of $\mathrm{N} /$ is the lack of uniformity in the usage of this sound by Ndia people. One finde a speaker who says haha' 'here' but Kis jo'knife' both of whith havefh! in weatern dialects i.e. hihs and Kàjo. If the bound was not borrowed there should have been uniformity in ito usage Note also that no Ki-Ndia speaker has generalized $/ \mathrm{h} /$ in all his/her vocabulary.

The split of te into /tsj and / / An these two dialects has followed a similar trend in all other dialects of this region. The difference does not occur in the split but in the changes that occured after the spift had taken place. As
occurred. All we know is that in certain onvironmonte et changed to / / while in others it remained as/ts/ (in Gichugu and iNdia). We suspect that one of the environments in which this sound changed to $/ \Delta /$ was $/$ /ate/. This change has been discussed under Dahl's law (see 4

In all other respects this group of dialects has had the sane changes as those of Ki-Mbeere - Ki- Fbi group. Wo, therefore, need not repeat what hae been disemsced earlier.
3.2.4 Ki-Mathira.

This dialect belongs to group of dialects that we are calling western dialects. This group consists of Ki-Mathira, Northern and Southern dialects. The three dialects are grouped together by a umber of features. These include the surface realisations of $[b],[d],[f]$ and [ B$]$ a feature that is not found in any other dialect or group of dialects, in Southern Mt. Kenya. The three are also grouped together by lack of a merger of " $P$ and " $B$ that we found to have taken place in eastern dialects.

The surfacing of $[b]$. [d], [J]and [ $c]$ in these three dialects is limited to a ingle environment ie. initial positions, These four sounds are generated by the deletion of initial gaels when they precessed a voiced stop. Historically these sounds are generated from $/ \mathrm{B} / ; / \mathrm{t} / \mathrm{F} / \mathrm{F} / \mathrm{ta} / \mathrm{F}$ and $/ \mathrm{K} /$ /s/ reapectivoly. Synchronically these are allophones of
/abs /ad/s/aj/ and / j es/ respectively. To generate the present day surface forms we have the following rules:-

After the application of rule 22 we get the following Bets of pairs:-
23. Bate
bèta
bot battalions $</ \mathrm{n}$-Bolo/ tuba bend
du?
끌
do sa
cana:
јпи ${ }^{\circ}$
Kane
gary
Kàjá
raja
need
ducks </n-Bata/
dacke </notum/
sight
skims </arroba/
make a mate
a mark </n-sama

- enol potato vine.
something for chowing /a-Eari-d
shout
divide
garóz turn
gáróz

From these examples it 18 clear that initial stops are generated in given morphological class ie. in nouns only. One say therefore wish to deal with the changes 1: morphophoneme form. In such an approach rule $2^{1 /}$ would be quite enough to generate the surface forms-
24. $/ B /$ [b]

This rule may seen quite adequate but it should be rejected for a number of reasons. First this rule is not phonological and should not be formulated as if it has some phonological motivation. It also creates a problem of motivation 1.e. we cannot show why the underlying sounds hare changed. With these and any other reasons that may arlen from the above rule we should reject the morphophosonic approach.

Having rejected rule 24 we return to rule 22 in which the motivations for the changes can be clearly shown. The motivation e for the changes are initial cluster simplification. in that we first have consonantal changes It is also easy to trace the process of the ch ages tenon nasal deletion. We should, also, note that in
medial positions the above sound a remain unchanged o. \& .
$/$ g-ro:a $/ \rightarrow$ 'ndo:a jo: If we prefix this wi ta ne 'It is' we get [oosndosa]'they are means'. The phonological approach reveals that initial simplification are phonologically motivated.

The changes that affect B separate Ki-Mathira from her eastern neighbours i.e. Ki-Gichugu and Kl-Ndie. In Ki-Mathira and in the Northern dialect ${ }^{\circ} B$ has shifted to /f/. In medial positions this sound fluctuates between $[\nabla]$ and $[B]$. If, in all medial position e, this sound vas realised as [J]vo would talk of initial voice dicniailation but this is not the ease. The reality is that many people have .. P both initially and medially. A for, people have [v] or[3]in medial positions but [ 1 ]initially. Since moet of the people have [f] throughout we have to choose it an the phoneme of this dialect.

The moet plausible trend of change is shown in 25 (map 3).
25. $B>[\mathrm{V}] /[\mathrm{f}]>/ \mathrm{I} /$

This change agrees with what we said about ${ }^{\prime} P$ in our -arles discussions. The stage at which $[v]$ and $[f]$ alternated could have attracted restructuring due to other sounds like $/ t /$ and $/ k /$ which did not change. In other words this could have been case or analogical levelling or paradigmintio regularisation.

As etated abova Ki-Mathira and its vestern neighboure did not merge ${ }^{\circ} P$ and ${ }^{\circ} B$. In these three dialects ${ }^{\circ} P$ shifted to $\mathrm{M} /$. For these dialects the change is in 26:-
26. $\cdot \mathrm{P}>/ \mathrm{h} /$ 。

Historically rule 26 is ordered before rule 19. The changes affeoting •B in this region are very recent innovation. As indicated above the ehift fron ${ }^{\circ} \mathrm{B}$ to $/ \mathrm{f} / \mathrm{has}$ not yot been coapleted by all speakers. The opinion of the writer 1s that ${ }^{-B}$ loss was the olde日t rulo. It was then followed by P-lenition and finally by the on going shift fron /B/ to /f/ in Ki-Mathira and Northern dialect.

An iuportant dialectal factor is that whereas the initial B loss was carried out in the whole region i.e. rule 7 the loss of initial ${ }^{\circ} \mathrm{P}$ did not affect western dialects. This could mean that $P-10 n i t i o n i s$ more recent in western dialects than in the eastern hialects.

As indicated in this chapter Ki-Mathira is alone in having /a/ where all other dialects have /d/. Whatever the reason is we have not jet established it. It way have come fromints which in other dialects changed to $/ \mathbb{d} /$. It may not be frov this source but from a borrowed sound -. g. - |s| which vas, first, voiced intervocalically and thon restructured into $/ \mathrm{s} /$. 01 these two the first altornative soen more plausible. Note that if this sound originated fron ints wo have no problen in explaining why vowels are
leagthened before it (ef. 3.2.2). The leagthening should be seen as conpensatory foature for the loat nacel.

The second alteraative is not supported by what happens to other voiceless counds i.e. $\cdot / 8 /$ and $/ 1 / /$ None of these two sounds is voiced iatervocelioolly. It is also not supported by comparative evidence. A comparisen between the dialeote showe that Ki-Mathira mas /s/ where other dialecte have / / This rules ont the idea of borrowing and leaves us with one alternative only. This is ats) $/ 2 /$ in Mathira while in other dialeote it chenged to /1/.

In cluncluding this secticn let un zote that any other changes that have not been discussed under Mathirs dzalect are taken to be the same as those discussed eariler.
3.2.5 Northern and Southern dialects.

As otated at the begianing of 3.1 .5 taese two dialecte are grouped with Ki-Mathira by the rule of initial nasal deletions. After the deletions the three dialecte have $[b],[d],[f]$ and $[g]$ as allophones of $/ \mathrm{mb} / \mathrm{g} / \mathrm{ad} / \mathrm{g} / \mathrm{nj} /$ and $/ \mathrm{g} /$. These dialects are, also, grouped with Ki-Mathira by the prosent dietinction betveen *P and ${ }^{-B}$. The only major deviation froa Ki-Mathira that those two dialects share is the lack of $/ \mathrm{s} /$ in their sound structuree. In this reapect the two dialects agree with eastern dialecte by having / / /

Between themeolves the two dialects differ in that the Southern dialect has $N /$ where the Northern dialect has /8/. Because of this difference Northern and Ki-Mathira dialects go together while Southern dialect is grouped with Ki-Ndia and Ki-Gifchag. The changes that affect these sounds have been diecnesed under Gichugu - Nadia group and under Mathira dialect. We need not therefore go back to then. The only thing that we should note is that since the original Bs were lost in all environments except after nasals we need a rule to generate the present day $/ B / E$ in Southers dialect.

The most plausible argument would be that after ${ }^{\circ} B$ was lost in all non-nasal onvironwonts some levelling occured which reintroduced $/ B /$ through paradigmatic regularization. The change can be formulated as in 27.
27. $b>/ B /$ morphemes with \#mb.

This [b] vas from the original * in nasal environments. The motivation for rule 27 was to level the paradigms with *ab which were analogous to those with \#ad; Win and \#go
 to alternate with wile \#ab had sone. To reintroduce /B/ rule 27 was to be seed which van an inversion of en earlier rule. The two rules 1.e. 27 and its predeceneor can be formulated as in 28.

Note that "B was lost in the same environments in which it han been rointroduced. The differonce is only that it ves not reintroduced in the same morphones.

To support the clain that sowe Be were lont we have the following examples:-

In Soutbern dialecte the above roots would all surface vith $[\mathrm{r}]$ inetead of the Ki-Bbu [ $]$. The reason for this is that Southern dialect has levelled all rowel initial roots as if ther bas / / / . The K1-Eabu surface forms show us that the origunal 1.0 . the proto root had a bilabial filcativ. In Ki-Eabu as in all other dialects the bilabial sound was lost but the derivation functions as if it is still present.

Examples in 29 contrast with those of 30 in that those 0 of 30 can be shown to have a roiced bilabial fricative. Note the difference between class $9 / 10$ and classes 7 and 12.

| 30. C1ass 9/10 | $\mathrm{Cl}_{388}$ | Clase 12 | Q1088 |
| :---: | :---: | :---: | :---: |
| /Mtori/ | KoBori | Kabori | goet. |
| Mbiro/ | Kebirj | nidir | scot. |
| Mbake 6 | KeBake | Kabake | tobacco. |
| Mbugi! | Kebusi | KaBuei | coll (on atival) |

All the examples in 30 are found in western dialects except that Ki-Mathira and Northern dialects will have /i/ In classes 7 and 12. The Southern dislect wil have /A/ as shown in the examples. In subu and Mbeere classes 7 and 12 will have $N /$ while Gichugu and Ndia will have/B/. All the dialects will have $[b]$ in class $9 / 10$.

To go back to our clais of the reintroduction of $/ \mathrm{B} /$ we note that this sound has been reintroduced in the roots that have[mb] There is no evidence to show that/B/has been reintroduced in the morphemes in which it was lost. This was not to be expected.

In conclusion or this section we should point out that there seens to be a tendency for many dialects to elieinate the bilabial, Iricatives. This is aainly true of Ki-pubu Ki-Mbeere, Ki-Mathira and Northern dialects. There seen to be a preference lor labodental sounds. Thus in the Ki-Embu - Ki-Mbeere group both •P and $\bullet B$ change to $/ V /$ and in Ki-Mathira - Northern dialect grupp changes to /f/e The changes experienced here support Honikman (1964). Honikman sayo:-
'all languages do not have identical articulatory
setting: wheress one languge may resemble another in
this respect, others may differ considerably."
In our region of study we could substitute the word
language for dialects. Mcst dialects agree in this respect
of eliminating bilabial Iricatives but three of them
ie. Gichugu, Nadia and Southern dialects have not gone the same way. It may be they will follow suit but as of now we have no evidence to rake any judgement.

Another interesting phenomenon is that there are certain Be that have been replaced by [j]. These include gala: Pron Protomantu 'g aba 'divide.' Whether this [J] has been introduced through epenthesis or by a regular sound change has not been established beyond reasobale doubts. Guthries says that the change is a regular one but does not discuss the environments in which it occured. Our doubts stem from the fact that we have a synchronic rule of [f] epenthesis (cf. 4.14).

### 3.3.1 The rowels:

The vowel structure is very much like the proto $S$. Mt. Kenya vowel structure. In all the seven dialects one can -asily establish seven vowels. If one considers length ain dialect will have a minimus of forgoer vowels. These vowels play no rete in dialect classification. The only vowels that help to establish dialect boundaries are the nasalised rowels of Ki-Mathira.

Looking at the novel structure of PB, one could postulate the following changes in S. Mt. Kenya-

```
31.1. /i/< & y>/u/ 7.
    2. }/0/<1\mp@code{n}>/0/6\mathrm{ .
    3. /&/<< 0 0>/コ/5
```

AE indicated in 32 (above) all the vovele except ${ }^{\circ}$ a have been lowered. Only "a han not been lowered because it is as low as it could possibly be. The above changes have occured in all the dialects.

### 3.3.2. Long rowel 6:

When discussing the long phonemic vowels we have to distinguish them frow the phonetically conditioned long vowels. The latter are discussed elsewhere in this study (cf. 4.2.5d. The former will be discussed and exemplified in this section.

In this section we shall not concern ourselves with the long vowels of f rotomantu ( PB ). Our main concern will be to establish the total number of phonemic vowels in the dialects of S. Mt. Kenya. In these dialects we have phonemic distinctions between long and short vowels. This means that instead of having seven phonemic rowels we have a total of forteen. The long vowels are exemplified in the following examples (see 32).
 the examples given in 32 are not enough to establish a distinction between long and short vowels. It is for this reason that we have provided the following parsi- (see 33).

## Gichueu Ndia Mathira No dialect So dialect Glnsg

drear

With these and many other examples wo can now dray a rowel chart for the above dialects. The chart shall include al 1 the phonenic vowels of S. Mt. Kenya. This is shown In 34.

as stated earlier this makes a total of forteen phonemic vowels. Whether this system cones from PB or not 18 not relevant to our discussion.

### 3.3.3 Nash vowels:

Vowels are generally nasalised when they occur between non-anterior nasals and prenasalised voiced consonants. In features this rule can be formulated as in 35.
35. $V \rightarrow[$ +nasal $] / C$

C C

$$
\left[\begin{array}{l}
- \text { continuant } \\
+ \text { nasal }
\end{array}\right]-\left[\begin{array}{l}
\text { nasal }
\end{array}\right][-n \text { - sal }]
$$

In this section we shall not deal with this type of nasalization because this 18 synchronic. We shall deal with sone nasal rowels that seer to occur in sone non-nasal environments.

The nasalisation to be discussed here is unique to Kd-Mathira dialect. In Kı-Mathira wo find sone nasalised
vowels before / / or / / for those who have replaced / / / with / / . The present day ntructuren do not show any nasal segments before this sound but sone comparative study shows that there may have been a nasal segment before this sound. With examples we shall compare a number of dialectal forme so as to find out what may have caused this nasalization. The examples are given in 36.
36. KioEmbu Ki-Gichugu Ki-Mathira N. dialect Gloss

Frow these dialectal forms we see that in $\kappa 1$-最bu and Kı-Gichugu we have nasal clusters while io Ki-Mathira and Northern dialects wo have long vowels. This length seems to replace some lost clement which, in this case, could only be a nasal.

Our interest in discussing this feature is to find out what its phonemic status is. Before coming to any conclusions wo should rake a for comments about the occurence of these nasal vowels. The most interesting observation about this is that these nasals are found before this sound only (ice. before $/ \mathrm{z} /$ ). The other interesting observation is that sone people have a tendency of naneliaing other vowels before this sound. There are others, also,
who tend to nasalise / / only. Tvo of my inforaate had the following pattern.

Informant $A$ is a postgraduate student in the Oniversi $y$ of Nairobi and Infurmant $B$ has just finished hor secondary -ducation. The two infomants are very close relatives and come from the same village. When I asked them who would ว̀sé etce they claimed that that would be 'Inner Ki-Mathira' 1.0. peopl. who come from the area north of Karatina Nyeri road and especially north of Karatina.

These two informants have different types of vowels. The firet one tende to nesalise the two long vovels before /d/ while the second dietinguishes between $/ \supset V$ and $/ 0: /$ This raises a number of questions whioh inelude (a) whet is the criterion of choosiag the vowel to be macolised? (b) in not masalising /os/ is the cecoad informant showisg some morpholexical or sound differencenf

It may be that the firet informant is geaeraliaiag the naselization of vovely before /s/ or / $/ \mathrm{d} /$ wile the eecond has learned these words as different. For the eecond informant there may be a small set of words that heve to have nasalised vowels. These vords beloag to given clase

## 126

of vords. The first informant may be oxtending the once linited rule to other lezical items. The queetion that seons to be of crucial inpertance to us, is how ve vant to account for these fow ancal rowels, whict for some people are linited to worde corresponding to nacal clusters in other dialecte.

Since we have not jot got a case where minimal paire can be established we foel that this should be treated as an interaediate change. This is a midway stage betwoen the loss of nasal elements and the establishment of phonesic nasal rovels. The change could, also, fail to materialiso but load to a merger botweon thes masal vowels and long vovels wafch alreaay exist in the dialect. This is the nost likely thing to happen especielly due to extrelingaistic pressures like status of other diuleste, writton language otc.

We propose the listing of these words with nasel elements and then delete the nasel after vowel nasalisation. This seems to be the mot logical approach until winimal pairs can be detected. Note that this case differs from the French nasel vowels discuseed by Schane ${ }^{5}$. In Schane (1971) a case was ostablishod for the nasal vowels to be, aynchronically, treated as phonemes. Kere wo have not jot reached that stege. Until the changee extend further wo have no need to have nesal vovels in our chart.

## 3.4 .1 TODQ

This section will deal with the role of tone in dielect clasaification. The type of tone differences that we shall discuss will be limited to the word level 1.e. tone in the lexical iteas. The reason for this is mainly because syntactic tone patterns require wuch more rasearch than we have done. The second reason is that a large amount of syntactic tone analysis has been done by my colloaguo Dr. Ford (cf. For 1974) ${ }^{6}$ which covers quite a large area of our region of atudy.

In S. Mt. Kenya tone plays an important role in dialcet classification. One will easily be detected as a atranger If he uses the wrong tone patterns in a given word or set of words. If for example a speaker places a high tone where the looal people place a low tone, in a word, he will be eacily mown to be a non-native apeaker of that dialect. He may also have the wrong tone sequences e.g. high, low, high, in a word wose pattern is high low low etce

The problen of tone patterns or tone sequences is most dieturbing in worde that mey have identisel cound etructures in two or more dialecte. When a epeaker of one dialect realises that the vord hac identioal cound -tructures, in the neighbouring dialect, he assumee that the tone is the sala. When he is corrected he fails to see what is being corrected. This problem arlaee because difforent dialocts claseify vords differently. A word
that begins with . Low tone in one dialect may begin with

- high tone in another dialect and have a sequence of two high tones in third diale-t. In order to exeaplify this eituntion we have examples in 38.

In words which have no sound differences but which have tone differences tone alone vill be enough to set dialect boundaries. In the word for pierce Ki-Mbeere speaker will know that you are a stranger if you have a high tone in the last syllable. Sometimes he way oven toll you where do jou come from. My K1-Embu informants were able to tell we that I cane from 'Gikuu' when I said [ato'] for Ki-Enbu [moté]'tree'. Such correctione were comon to me when I tried to learn tone patterns of my informante.

The diaturbing thing to dialect learner is that in one word one may be corrected for producing a eequence of low high ingtead of high low and in the next word be corrected for producing a sequence of high low. This can easily happen because dialects have different tone clasees (cf. Ford 1974).

The only solution to this problem is for one to learn the tone patterns and tone classes of the rative speakern. The difference between such e learner and tre native speaker is that the native speakers' patterns are produced naturally 1.e. no efforts are made to ranember then. The learner must make offorts to leara anc koep tha patterms.

Ki-Matinira N. dialect S. dialoct Gloss

In conclusion of this (tone) section let us note that even fron the above short list of words we can see a distinction betweon eastern and vestern dialecte. The western dialects tend to have more words with a sequence of low, low high tones than their eastern brothers. This may be due to sowe influence fron some noighbouring lenguages. I have not done any comparative tone analyeis. Dr. Ford (personal commaication) has informed me that Massai has a lot of these initial low tone sequences. Whether this is the reason for the existence of these low tone soquences only research will tell.

## Footnotes:

1. Guthries in his comparative Bantu vol. 2 of 1971 lists'Kikuyu' and 'Embe' only as the languages of Sourhter Mt. Kenya. There is no mention of any other dialect.
2. For Embo, Guthri• (1971) vol. 2, says, 'siailar to E. 51 but * $p>B(p, 4$ ). Thía may have been reant for Gichugu and Ndia dialects. These are the dialecte for which this change can upply. In prabu and Mbeore the change should have been $P>V$. Since he did not show that we asaume that Guthrie aistook Gichugu and Ndia for Embo.

This claim about Guthrie's wistake is supported by the old political divisions of the region. By the tiee Guthrie did his research these two dialects (i.e. Gichugu and Ndia) wore in Eabu district. If Guthrie intervieved aichugu informant but who by then was in Embu dietrict he could easily record the wrong information.
3. Hinnebusch (1973). Hinnebusch argues that Guthrie'a failure to differentiato between small and large groupe in Bantu languages stems from his (Guthrie's) disuisesal of the historical method. Hinaobusch has gone further, in subgrouping, than any other bistorical linguist. Ris is, to myowledge, the first aajor work to depart frow the earlier types of classification.
4. According to Kinnobusch (1973) P-ienition separates Swahili from other Kenyan coastal languages. This rule puts Swahili in the same group with som Tanzanian languages such sos Nengeroko, Rufijl, Matumbi etc. He further claims that this rule is, 'characteristic of a large area of Bantu', (Minvebuech 1973:220).
5. Schane S. (1971). In this article Schappe argues that synchronically wo have oral and nasal vowels, in French. He cites minimal pairs such as the following:[bon ami] < Mon ami 'good friend'. [by kamarad]</bon camarade/ 'good friend'. [äbyen ami] </ancien and/ 'old friend'. [aye manarad]/anoion cemarade/ 'old friend. Such examples as these prove that we have surface contrast between oral and nasal vowels and this contrast should be accounted for in our theory (language 47:3). The Mathira vowels have not jet reached such a point of surface contrast. We should therefore not treat them en anlace contrast until further developments have been detected.
6. For those interested in the grammatical :enturas of tone Ford (1974) is highly recommended.

## CEAPTER FCUR

## Synchroaic Phoadear.

4.0 In chapter III we dealt with comparative phonology and the diachronic rules thet have led to the existing sound differences. We did not deal with the differences that we experience in synchronic phonology.

In this chapter (IV) we shall concern ourselves with differences that occur in phonological rules of the present day gramars. Most of the rules that will be discussed play a major role in dialect clasaification. A Zew of them will be cited as examples of common linguistic phenomena that put all these dialects into one group.

One major difference between this chapter and the preceding one is that in chapter IV no rale will be discussed unless it is in the synchronic grariaars of this no region. It must also be phologically motivated. This means that no diachronic, morphloogical or syntactic rules will be dealt with in this chapter.

### 4.1.1 The syllable.

Our discussion of the phonology will begin with the syllable. The theory of 'syllabic phonology', has been advocated for and incorporated into the phonological descriptions by a number of scholars. Thosevto have incorporated it into the Natural Generative Phomolosy include Vennemann (1973) and Hooper (1973). Other echolars

56
-.8. Kiaberth (1969) and Brown (1972) have diecuesed ejllable Etructure and sjllable types rith hope of showing that the syllable is an iaportant concept in cenerative phonoloco. These sholare have shows that without the use of the osllable cortain lingaiatic ruies vill aise adequate seneralisations or eotivatione. In this section short discussion of the syllable types found in $S$. Mt. Konja dialects vill be giren. The relevance of syllabification to dialect boundaries is also discussed.

As noted by many linguists, c.f. Kisberth 1969, the woet universal eyllable type and therefore the moet unameked 1s CV. In Bantu languages this syllable type is more general than any other syllable types. The dialects of our study are not exceptional in this respect. Thougn these dialecte have consonantal clusters, whey are of a restrjcted type.

The clubtering of consonants apeara differently in different languages and language groups. Each language or group of languages uses difforeat atrategies to get rid of undesired consonantal clusters. K1sberth (1969) ${ }^{1}$ shown. very clearly, that the openthesis rule ia Iawelmani is aised at breaking up the disallowed clunters. A similar rule was discussed by Hooper (1973). Hooper' epenthetie rule breake consonantal clusters found in worde that are borrowed into Spanish.

As will be seen later epenthesis, vowel coalescence, assimilation etce, are sone of the strategies employed by
the above dialects in order to achieve the preferred syllable structure. These strategies are noflections of the operations of the strong constraints that human languages impose on their phonological structures. These constraints have to be there as chocks on what other rules and components may do.

There is general assumption that the dialects of Southern Mt. Kenya have identical constraints on syllable structure. This assumption has been brought about by the readings of the available grammars egg. Barlow (1960). It is not an assumption cultivated by field work within the region. Field research shows that there are fundamental differences especially in the treatment of a sequence of alveolar nasals and anterior continuants. There are also differences in the treatment of initial nasals (cf. 3.2.1).

In Eabu one finds a tendency to syllabify anterior nasals when they occur before $/ \mathrm{V} /$ and $/ \mathrm{d} /$. These nasals are the first person singular and class $9 / 10$ markers both of which are marked by \{n\} . ~ A ~ c o m p a r i s o n ~ b e t w e e n ~ $K 1$ - H bu and Ki-Mbeere will help to clarify:-

| 1. Underlying | ni-Eabu | Ki-Mbeere | Gloss |
| :--- | :--- | :--- | :--- |
| /neva/ | Yrá | va | 'give' |
| /n-vunda/ Mrùndá | mbùindá | 'donke y(o)' |  |
| /n-varika/ Mráriká | mbárikà | 'she goat (s)' |  |
| /n-datal pdàtá | ndátà | 'barren Woman |  |

In features the rule can be formalised as follows-

$$
\text { 2. }\left[\begin{array}{l}
C \\
{\left[\begin{array}{l}
t a s a l \\
+a n t .
\end{array}\right] \rightarrow[+\operatorname{yllabl}]}
\end{array}\right] /-\left[\begin{array}{c}
c \\
+\operatorname{con} \operatorname{sonan} t \\
-\operatorname{top} .
\end{array}\right]
$$

mule 2 syllabifies anterior nasals when they occur before anterior consonants. This leaves the volar continuant out. The velar continuant is alvaye changed into atop after a nasal.

The syllabification of nasals in 2 is not at strong ac the syllabification of stressed nasals in Ximahili. The Kiewahill syllables are much stronger than the Kl-Embu ones -.g. Kiswahili Mi 'tree' Mu 'person'. The Eabu nasals are not as clear as the Kiswabili ones and oven when they are clear they are found in very few people's spesch.

The surfacing of the sequences of nasals and continuate seems to be recent innovation in Ki-Enbe. This fact is revealed by some forms that have voiced stops after nasals. These forms includes-
3. [Mbolí] goat (s)

| [Mbwé] | grey hair |
| :--- | :--- |
| [Mbùrá ] | raise |
| [mbjég ] | buffalo. |

These forme lead to number of suggestions. On of these suggestions is that the rule of nasal assimilation
which generated these form goes back to a tie when ${ }^{\text {B }}$ was still a phoneme in the dialect. If this is true then the rule that generates the above form is a case of rule morphologisation. It is morphologisation because "B is so longer a phoneme in Ki-Pbu and jet vo do have surface forme with it.

The second suggestion is the one referred to above i.e. the generation of nasals before continuance is an innovation in Ki-Embu and that the rule is being borrowed into Ki-Mbeere. This innovation is likely to lead to the restructuring of the forms in 3 or a split between / $/$ /and $/ B /$ as two different phonemes.

Examples in 3 reveal a serious limitation on the types of segments that are allowed to cluster into one syllable. There are two clustering conditions and cen be stated as in 4 ( $S$ stands for segment):-
4. (1) If $f$

e.g. [Mboli] goat (s) [Move] grey hair.

The fixing of syllable boundaries where there are sequences of vowels is handled differently by different dialects or age groups. Some dialect e have more eeriotas constraints on syllabification of sequences of vowels than others. These constraints are, mainly, put on what vowel
heights may occur in sequence. In Ki-Mbeere, Ki-Enbu and Ki-Gichugu dialects, initial and medial syllables have highly restricted sequences. The most frequent sequence is /attu/ which surfaces as a $\$$. Most other clusters are intolerable. Some clusters such as $\$$ ai f are not found in any native words that $I$ know of.

These three dialects use a number of strategies to get rid of any undesired vowel clusters. These strategies include total assimilation of the second vowel into the first one (cf. 3.f.4). An example of such total assimilations is /e/ changing into $i$ before, i erE. Ko-imbal Kiimba 'copse'. This chan e is limited to these three dialects only. A second strategy is the gliding rule (ci. 3.1.4).

The other four dialects do not reveal similar constraints on syllable structure. Here a wider rance of vowel sequences is tolerated. The sequences include:- ai, au, ea, ia, ai, we, $i, 0, u, t, i, e t c$. All these sequences can occur in the same syllable without the change of the first rowel, into a glide. The eastern dialects of Ki-Mbeere, Ki-Embu, Ki-Gichugu and Ki-Ndie (unschooled people only) tend to glide the first vowel in most of the above sequences. Where such sequences are allowed to occur they are in different syllables egg.
5.
Eastern dialects

In Western dialects both age and dialect boundary play important roles in the syllabification of sequences of vowels. In Ki-Mathira and the Northern dialects sequences
 $\$ \mathrm{ke} W$ a C [- voice] in the speech of old people and as Figea ${ }_{[-\operatorname{coi} 00]}$ in the speech of young people. eng.

The voicing of $\mathrm{k} / \mathrm{f}$ in 6 (1-iii) by young people, means that /eta/ are put into one syllable. This lead to the voicing of $\mathrm{N} / \mathrm{d}$ due to Dahl's law. The old people on the other hand put the two vowels in two different syllables hence no voicing of $\mathrm{N} /$. Note that in old people Dahl's lav hes operated just as in young people but due to different syllabification tace surface forme differ. This age phenomenon is similar to that of Maya's palatalization rule. (ci. Byarushongo 1975) ${ }^{2}$.

### 4.1.2 Vowel Clusters.

As shown above syllable boundaries and syllable structures are not random phenomena in any language. It was noted in 4.1 .1 that the noet unasiced syllable is 汭Y but we aleo have other syllable types. Some of these, other types, are highly marked •.g. syllabic nasals given above.

Among the syllables made up of vowels only the most comnon ones are \$VF and \$VV\$. The first type is found in vords like ['̀ná]'see' while the second type is found in words like [aume']'he bas gone out'. As vill be noted later the second type of eyllables is not common in $S$. Mt. Kenya.

In the previous section it was noted that the eastern dialeots disallow nost of the vovel sequences that weetern dialects allow. The eastern dialects and especially Ki-Eubu, Ki-Mbeere and Ki-Gichugu rowel coalescence and vovel gliding are common etrategies that are used to get rid of the undeaired rowel sequences. The first of these strategies is exemplified in 7.

In the prefix positions Ki-Enbu, Ki-Mbeere, Ki-Gichugu
and Ki-Ndin (eapecially old and uneducated people) use the sane strategios. As shown in 1 this rule applies scrose formative boundaries. The sane is not tree of the vestern dialects. In vestern dialeots front vovel is usually glided if it occure before aback vowel e.8. /eta/[ja]. In very slow speeches the two vowels are kopt diatinct. We ahall cowe to vowel glidiag shortyly.

Looking at the examples in 1 we note that in one case the front midhigh vowel i.e. /e/ in deleted before [0]. In another example /e+a/ change into [0:]. This raises doubts as to whother what we have is vowel conlescence or some type of levelling. It nay be that this is a case of levelling that began as a phonological rule. Note that we have aine /a-in-c/ 'let hiv sing'. If vowol coalescence was a general rule we should have E EnE.

The aurfaciag of $[a i]$ in $[a+a r]$ and the deletion of fo/ before $[0]$ wakes this rule have meny exceptions. These exceptions make the forwalization of the coaleacence ruie quite complicated. We should leave this rule unformalized until its phonological status have been established beyond reasonable doubt.

Earlier on we montioned vowol gliding. We claimod that front vowela are glided if they occur before back vowels. This rule has been discussed under vowel aseimilation and rowel diesiailation (cf. 3.1.4 and 3.1.5).

In suffix positions the eastern dialecte are divided into two subgroups. These are, the Ki-Mbeere -Ki-Robu group and the Ki-Gichugu - Ki-Ndia group. In Ki-Mbeere - Ki-Embu area a rule of consonantal epenthesis is applied to break up rowel clusters that occur medially. Tbe wedial clasters that notivate epenthesis are made up of a non-iow rowel followed by low rowel i.e. $[$-low $]+[$ low $]$. In features the eponthetic rule is:-

Rule 8 inserts a consonant between the root and the habitual tease morpheme. Tho habitual tonse morpheme is aga - For exempification see examples below:-
9. Unterlying Ki-Bebu Ki-Mbeare Gloss

| /a-ogu-aga/ bogufaga mbegusaga | 'I often hear' |
| :--- | :--- | :--- |
| /a-die-aga/ adietaga adiobaga | 'He often goes' |
| /a-re-aga/ aresaga aresaga | 'He often eats' |

The moat irequent environmente in which this rule operates are oreated by the above morphene but we have reasons to judge that the rule operates any time its Structural Deficription (SD) ie met. Thie is revenled by the operation of the rule in such forms as /ve v $\varepsilon$-ana/ včánà 'give each other'. This form surfaces difforently in difforont dialects e.g.
10. Kimbeero-KiEnbu KiGichugu-KiNdie The reet

The Ki-Embu-Ki-Mbeere forms in 10 reveal that even When the two vowels are bothlow the rule will operate. We need to specify further that the only time when the rule vill not operate is when the two vowels are identical e.g. /ata/ which surfaces as [ai]. In the two dialects we have Araana/ [ká:nà] 'deny', Na-anal [kà:nà]'child'. These forme confira our claim that when the two vowels are identical the epenthesis rule is not applicable.

In initial positions vowels of different heighte are allowed. These sequences include /au/, /a/etc. The pirst sequence ocerrs in ['aúgà' hé has said', and [àn'i] 'he has seon'. These forms are not counter exanples to our clain about epenthesis because they do not generate medial vowel clusters.

Examples and discuseions given above reveal thet epenthesis is motivated by eyllable structure constraints. These constraints disallow the geacration of any aedial byllable With two vowels of different heights. Even two separate eyllablee in aedial position are dieallowed if they have two vovels of different heighte occuring adjacent to each other.

Another fact revealed by the above disoussion and

#### Abstract

examples is the role of this rule to dialect classification. Epentheais oeparates KlMbeere and Ki-Eabu Pron Ki-Gichugu and Ki-Ndia. Abit will be seen later Kis'ichugu and Ki-Ndia use a different strategy to overcome the ramo problea.

In discussing this rule one sees an interesting: siailarity between this epenthusis and Hooper's (197z example in Spanish. For Spanish the rule changes structureo from /CCV/ to CVgClg. Our Ki-Mbeere - Ki-Embu rale changes etructures frow/CV-VCV/ to $[\mathrm{CV} \mathrm{CV} \mathrm{CV}]$ proferred oylleble structure.

### 4.1.3 Consonantal assiailation.

Assimilation is dofined ae a procese by which a sound acquires features of another sound i.e. adopte features from another sound. This process takes place, maully, when the two sounds are in contact. The opposite of this is dissimilation (see 3.1.4.1). In this section we shall deal with assiailation of consonants in the dialects of this study.

There are two main types of aseimilation of consonente in the dialects of Southern Mt. Kenga. TMese ares-

1. Assimilation to the point of articulation.
2. Assidilation to the manner of articulation.

The root general of these two is 1 which is found in all the dialects. This type of eselimilation mainly afiecta
the nasals. Nasal consonants assimilate to the point of articulation of the following consonants. In features the rule is formulated as in 11:-
11. $\mathrm{c} \rightarrow$ [appoint] $/-\mathrm{c}$
[+nasal] [point.]

This rule is found in all the dialects of S. Mt. Kenya but with minor variations in some dialects. These variations include the generation of $[M]$ before $/ R /$ and $/ V /$ in some dialects. This is variation in that according to rule 11 we expected to find[ $M$ ] in these environments i.e. before $/ \mathrm{f} /$ and $/ \mathrm{V} /$. The variations are found in Northern dialect and in Ki-Mbeore respectively. For these speakers the rule misses an important point by failing to show that $/ n+f / a n d / n+v /$ will surface as [ mb], for these two areas, and not the expected " $\mathrm{y} V$, "If or " MV . This peculiarity has to be accounted for in our phonological theory.

To account for the generation of $\quad \mathrm{b}$ from the above underlying forms there are two possible approaches. The first one is to incorporate the archisegment into our linguistic theory i.e. N.G.G. This has already been done by Hooper (1975). With the archisegment the underlying forms for the above surface form will be $/ N+1 /$ and $/ N+N /$. Frow these forms wo shall get [ab] after the application of the necessary rules.

The second approach is to treat the rule as a morpholo-
gical one. As a arpholegical rule one appeals to the historical development of the labial sounds of S. Mt. Kenya. Historically it is possible to prove that bots /s/ and /v/ come from " $18 /$. At the time that these two sound were realised as •/9/ rule 11 was a true generalization in all the dialects. This is still true in Ki-Gichugu, Ki-Ndia and Southern dialect.

When */b/ changed into / / / and /V /in some dialects the old products of $\cdot / \mathrm{n}+\mathrm{b} / \mathrm{n}[\mathrm{b}]$ wore retained. The retention of the same surface forms even when the sounds had changed shows that the rule was morphologised. It wat tiered ae a rule that generated a class of morphemes which med not changed.

Morphologisation of rule 11 seems to have been a general feature of Ki-kubu phonology at one stage. This le still retained by some speakers in a few old structures. Compare the Kiminbu forms in 12 with those of 12b.
12. (i) emboli /n+rori/ goat (s) cl. 9/10.
(ii) mbjesj $/ \mathrm{n}+\mathrm{Frgo} / \mathrm{bulfalo(es)} \mathrm{cl} 9 /$.10 .
(iii) mbá /nova/ give me 。

This acme dialect has:-
12. b (i) Mvuinda /ntvunda/ donkey (s) cl. 9/10

| (ii) Mrotá | $/ n+v o t a /$ | hunger | cl. $9 / 10$ |
| :--- | :--- | :--- | :--- |
| (iii) Mré: | $/ n+v o /$ | palau) | cl. $11 / 10$. |

For some Ki-Eabu speakers 12a (iii) is pronounced as va. The change from mba to va shows that the rule of nasal assimilation is gaining generality of over morphologization.

The struggle between rule morphologization and rule generalization is limited to Ki-Embu dialect. This is the dialect that has labiodental nasals. Other dialects ie. Ki-Mbeere and Northern dialect e have kept the morphologized forms unchanged. Whether or not a similar situation will arise in these two dialects remains to be seen.

Nasal assimilation plays an important role in establishing dialect boundaries. This rule classifies Ki-Mbeere Northern dialects and most of Ki-Mathira in one group i.e. the group with morphologization. The same rule classifies Gichugu, Ndia and Southern dialect as the group with a general assimilatory rule while Embus is in both the general rule and in norphologization.

## Another rule that affects the consonants is that of

 palatalization. this affects voiceless velar stop only. A voiceless velar stop becomes palatalized when it occurs before front vowels ie.13. C

$$
\left[\begin{array}{l}
C \\
\text { +high } \\
\text {-cont. } \\
\text {-voice }
\end{array}\right] \rightarrow \text { +palatal } /-[+ \text { front }]
$$

The vowel meet be marked [+front] and not [-back] because our vowels include / M which is [-back] and [-front]. For this reason we have to make sure that our rule is restricted from applying to $\mathrm{Ak} / \mathrm{s}$ before / $\mathrm{Q} /$. The operations of rale 13 are show in 14.
14. /kiva/ [kiva] 'Shat up.'
kennel [koama]/[kyama] 'council'
/na/ [pena] $[k \in n a]$ 'be happy'
The variation e between [ḳeana [kana] and $\underline{k}$ knell]/
[kina] are determined by dialect boundaries. The eastern dialects tend to glide high vowel while western dialects kop it separate but in the same syllable with the following non high vowel.
4.1.4 Vowel assimilation

Assimilatory rules that affect vowels are different frow the assimilatory rules that affect consonants. The major difference lies in that no cases of total assimilation exist in consonants but we have some in vowels. It will also be noted that assimilation to the manner of articulation differs between the two groups of sounds. Consonant e become voiced when the occur after nasals but no vowels become voiceless when they occur after voiceless consonants.

There are two major vowel assimilation process.

1. Partial assimilation.
2. Total assimilation.

It is obvious that the above examples have the sane sound structure in all the dialects. The main differences occur in the tone structure. For the differences in tone structure a 8003.4 .1 . 'here is also a minor difference in the quality of the initial vowel of 15(iv). The discussion of morphological differences was given in 2.2.1.

In situations where two derivational front vowels occur in a sequence the second ic alvaje changed into a palatal, slide. This may bo another atratocy of getting rid of medial vowel clusters. If this wee not the case the following examples would have attracted epenthesis between the two front vowels.

The gliding rule operates any time its structural description is met. In order to make sure that no - epenthesis takes place in the above environments, which would be ungrammatical, our gliding rule must be reformulated as in 3 below:
17. $v \longrightarrow$ [-syllabic]/ $\nrightarrow \mathrm{V}$
[front] -front.
Rule 17 will glide any syllable intial front vowel if the following vowel is nonfront. Rule 17 does not, in any way, prevent epenthesis to insert a glide between two derived vowels if the epenthesis rule applies before the gliding rule. To avoid the insertion of [j] between two derived front vowels we have to formulate our epenthesis rule ina way that makes it apply after syllabification has taken place. The $[J]$ insertion rule has to be as follows:-
18. $\varnothing \rightarrow[\mathrm{j}] / \mathrm{v} \quad \nless \mathrm{v}$ [+front] [+front.]

This rule will only insert a glide if there is a syllable boundary between the two vowels. Note that this rule cannot apply before syllble boundaries have been
fixed. This makes gide insertion rule restricted to near surfaces forme with two front vowels only.

The assimilatory mature of palatal glide formation
is limited to the point of articulation. The puling of
a front vowel into a palatal position is due to the bacinesa of the following back vowel but the assimilatory process is changed into dissimilation by the change of features from [+vobalic][firont] to [-vocalic] [-front].

The crucial thing here is the change from [+vocalic] to $\left[\begin{array}{l}-r o c \\ -\operatorname{cons}\}\end{array}\right] \quad$ Which is a dissimilation. The change of
this feature may be more important than the asoinlatory nature discussed above. This dissimilation changes the vowels from one major class to another thus becoming amber of another natural class i.e. the class of glides. Ye therefore should treat this case as one of diseinilation in vowels.

The second type of assimilation involves the raiding of vowels. The raised vowles are $/ a / / 0 /$ and $/ 0 /$. The raising of these vowels is dependent on the dialect under discussion. Some dialects will fail to raise /o/ but raise /a/ while others will raise /e /but fail to raise /a/. The following examples will show the dialect grouping:-

From these examples we note that Eastern dialectal fall to raise /a/ to [ $]$ in 1 -iii but raise /o/ to $[1]$ in vi. The Western dialects do the opposite by raising /a/ to[ $\varepsilon$ ]but keeping /e/ intact in vi. The case of $/ \mathrm{a} /+/ 0 /$ should be seen as both raising and lowering 1.e. reciprocal ascidilation whereby the two vowels collapse into $[\dot{E}:]$.

In the above examples we have total assimilation of $/ 0 /$ into $[u]$ before $/ u /$ and $/ 0 / i n t o[1]$ before $/ i / /(\ln$ the Easter dialects). We also have other cases of total assimilation that affect $/ \mathrm{a} /$. This happens when this Towel occurs before $/ 2 /$. This rule operates in all dialects but Eastern dialects have some people who tend to pas to assimilate /a/ to / $/$. Examples for this rule include.
20. ka-jnte/ kjinfc lame (cl. 11).

Distance between the two rowels, in height, and their differences in frontaess or backness seem to be the main reasons for the change. In general when two vowels are next to each other in height and if they agree in backness or non backness the lover one tends to be pulled to the higher

0ne. When the two vovels disagree in frontness or non Prontness they are likely to be left iatack e.g. kaigj〈/ka-is /' a saall heap', [koineral Mo-in-era/ 'to sing for.' The reason for the change of the vowels, in examples 19 and 20 , may be due to the fact that the same part of the tongue has to be used in their production. This makes their production anbit problenatic if they have to be kept distinct.

When the two vorel.s of the same feature in backness or frontness are changed into one the result is easier to produce than the input. The same is true of the two vovels thet colapse into a third vowel e.g. $/ a /+/ e /[\varepsilon:] / a /+/ 0 /$ j: $]$ etc. The force behind the changes is the problem of articulation of the two different vowels.

As noted above these rules have an important role in fixing dialect boundaries. The rules that colapse $/ \mathrm{a} /$ and /e/into[ $\varepsilon$ : $]$ do not operate in Eastern dialects while the rule that assimilates /o/into[i] does not apply in Western dialects. The sane is true of the collapaing of /a/ and /o/into[วs] which operates is vestern dialects only.

### 4.1.5.1 Consonantal diasimilation

Dissiailation is procese by which sounds become unlike each other. As with assiailation thís happens, in most cases, when the sounds involved in the process are

```
in contact. The word most, is used because there are cases
when dissimilation may involve two sounds that are not in
contact. In cases where the sounds are not in contact
they are usually in adjacent syllables. In this eection
we shall discuss both cases of dissimilatior i.e. sounds
In contact and sounds at a distance.
```

    First we shall discuss consonantal dissimilation. The
    only rule of consonantal dissimilation that we know of is
Dahl's law. This is a rule of voice dissimilation which
occurs in many Bantu languages. The rule in its most
general form occurs as in 21.
21. C

Rule 21 voices a $k$ /any time it occurs in prefix positions if the following syllable begins with voiceless consonant. In languages that have no voiced velar atop changes into a voiced velar fricative. In order to understand this rule let us look at the examples given in 22:
22.
underlying
No-kama/
Noo-tara/
/ko-ruga/

| H. dialects |  |
| :--- | :--- |
| Globe |  |
| gotama |  |
| gotama milk | to count |
| korugá | to cook |

Molina/ koine to sing

As stated earlier, Mo/ 'to' changes to and not
to go. This is because the dialects of this study have
no voiced velar stop. This may be a minor point but it
sakes rule 21 incorrect in that the voiceless velar stop does not only become voiced but it also weakens to a contrnuant. The fact that the dialects have no voiced velar -top should be stated somewhere in our grammar seas to take case of this change. This can be taken care of by inserting a statement in the sound inventory.

The uniformity shown in 22 is not always there. In western dialects we have cases where [so occurs before voiced segments. This is not true of the eastern dialects. The sounds that violates Dahl's law in wester dialects is /4/. The difference between western and eastern dialects is shown in 23.

The occurence of $e$ - before $/ 4 /$ raises a number of questions. These questions include: (a) Why should this sound be treated as voiceless sound? (b) What led to

#### Abstract

the split between the dialecte? The first question is more important to us than the second. It is important becauce this study is conserned with sound change and some sound change must have bean responsible for the above treatment.

In order to account for this strange behaviour of /d/ ve need look at its history. The history is revealed by a corparative study of the words that have this sound. The following words come from Kiewahili, Durama, Tharaka and Western dialects of S. Mt. Kenya.

| PB | Kiowahild | Duruma | Tharaka | H. dialecte | G2088 |
| :---: | :---: | :---: | :---: | :---: | :---: |
| CE | $n \mathrm{Ci}$ | - | nde | de | land, vorld |
| CANGA | meanga | mutsagga | moeajga | modanga | sand |
| CODI | Cozi | tsozi | reouri | reidori | tear of eye |
| YICI | MCI | mutsi | not | m0: de | pestle |
| PACA | paEa | - | ma: өa | 214880 | twin |

These words have the same meaning in all the above languages but differ in sound structure. Assuming, as has boen assumed in earlior works, that these languages originate from one mother language wo have a clear picture of poseible change from the original sounds to their present day forns. The changes are different in different languages. In the dialecte of $S$. Mt. Kenya the original sound has been voiced while in Duruwa Kiswahili and Tharaka the sound is otill voioeless. Even in our dialects of study there are some forme
which retain the voiceless sound. For exenplification of this we have forme in 25:

The presence of these forms suggest that the: orcured
a split of the $\mathrm{PB}^{*} \mathrm{C}$ into /a/ ane /iy/, in S. Mt. Koaya. The
latter shifted to $/ 8 /$. This prosence, of $/ \mathrm{d} /$ and $/ \mathrm{k} / \pi \mathrm{r}$ have come in two ways. The first possiblizy is th t all the PB */C/s silfted to / / in sove dialects with later borrowinge of / $/$ /f fran neighbouring dialects. The second poselbility is that sowe $P B \cdot / \mathbb{/ s}$ shifted to $/ \mathbb{/}$. in certain restricted eavironenta, which resulted into the phonemic aplit of the original sound. The latter poseibility can be confirwed by Tharaka exanples fron Iindbloe (1914).

According to Liadblow the only environment in which * C becomes /a/is after a nasal. If, by any chance, the nasale drop out wo are likely to got a eplit in Tharake. If this happened, in Tharaka, we should have $/ \mathrm{d} /$ and $/ \theta /$ Neither of the two possibilities has been proved vrons ia sound changes.

Regardless of whetever changes/to the present day aurface forws we still trace the original sound in the
following stages.
26. *C ざ te $\begin{array}{llll}0 & \text { d } \\ 1 & 2 & 3 & 4\end{array}$

It is not recessary that all the languages and dialects should take the same line of change. In the dialects of our study we have no proof that / $/$ / ever existed.

Fron the preceding discuseions and examples it is eridont that /a/ bistorically comes from a voiceless consonant. This explains why it is treated as a voicoless sound, for the purposes Dahl's lav. The behaviour of this sound orders the change from te to /d/after the introduction of Dahl's lav in the region. The violation of this rule in W. dialects means that the above change is a recent innovation. If all the dialecte had a general operation of Dahl's law we would find it hard to fix ita order in relation to the change.

If Bahl's lav had come into the region after the shift of - /ey to /a/ no dialect would have developed any exoeptions. Exceptions developed as a result of the failure to reanalyze the situation after the sound change had occured. Fallure to reanalyze the forms may have been caused by sore confusion as to what was the nature of the underlying sound. This vae especially so where the root had a volcelese sound but the derived forme had volced sounds e.g.

| 27. 5mbu | 4. Cialects | O1080 |
| :---: | :---: | :---: |
| So:ká | doká | go bad. |
| peloku | do:kú | bad cl ilio |
| S'okóra | Sokóra | make good (2 |

Note that Eikbu has an undorlying voicelese coasonant while western dialects have two underlying sounds. Ia V. dialecta the varb and the noun have roiced courds vaile the reveraive has a voiceless consonant. The Labu forws will all take go as their profix in the operation of Dal's law but western dialecte should if Dahl's lav was equally general, take both [ko] and [80]. This kind of behaviour of sounds ia deplorable in that one morphene has two underlying forms with two different prefixes. To avoid this deplorable situation all the vestern dialects tqke 80 for both underlying forme eg.
28. UndErlying
/ ko-ioka / / ko-sokora /
Y. dialects Gloss
[godo:ka] not koco.ka 'to go bad Ensoikera + to make good.

These morphenes show that restructuring wes not coapleted. The result was lack of uniformity in anderlying forms which led to lack of unfforsity on the surface. The speakets in their offorts to maintain uniformity Fiolated Dahl's lav. Onifornity of the prefixes is a deliberate offort on the part of adults - who keep on correoting children who begin by learning a goneral rele of devoicing imitial
sound if the root begins with a voiced sound. For the young language learners examples ind are [kodó:ka] and [gosóskora] but their parents and elder brothers and sisters keep on harassing them until theirs violate the rule. ${ }^{4}$

Having established the reasons for the exceptional markings on /d /we should now turn to our grammars and see how this violation of phonological rule is to be accounted for. In order to account for this change we have to accept one of the followings:-

1. Rule ordering
2. Restructuring.
with a grammar that allows extrinsic rule ordering like Transformational Generative Grammar (TGG) as exemplified by Chomsky and Bale 1968, we shall have the following two rules:
3. C

$$
\left[\begin{array}{c}
\text { + back } \\
+ \text { high } \\
+ \text { stop } \\
\text { - voice }
\end{array}\right] \longrightarrow[+ \text { voice }] \quad \mathrm{H} \text {-V voice }
$$

30. C

$$
\left.\begin{array}{l}
+\operatorname{cor} \\
+\operatorname{sat} \\
- \text { stop } \\
- \text { voice }
\end{array}\right] \xrightarrow{ }[+ \text { voice }]
$$

Rule 29 voices $/ k /$ in initial positiong if the root begine with a voiceless consonant and rele 30 changes $/ O$ to 4 in all environments.

While rules 29 and 30 are adequate for the date given one finds serious shortconings with their claine. Note that in this type of gramar /O/is taken as underlying sound but never surfaces in any enviroment. The choice of this sound as the underlying form for /a/ is based on the principle of the shortest distance but the realities of the examples given are different. he noted earlier that there is no prool that $/ 0 /$ ever existad in this region. W- also noted that there is an alternation between/d $/$ and /s/ <"tr within the dialectb that have violated Dahl" lav. The examples prove that the motivation for positiag /O/is formal elegance and not linguiatic realities.

If we have a gramar that disallows extrisaic rule ordering as exemplified in Vennemann (1973) and (1974) the bove rules will not be acceptable. In this type of gramear a clain is made thet restructuring has already taken place. Restructuring is established by, Vennemann'e (1973) the etrong Naturalness condition, which claime that, 'Lexical representations of non-alternating parts of morphenes are identical to their phonetic representation' For thís grampar the data discussed in this section will be accounted for by rule 31 \#:
31.

C

$$
\left[\begin{array}{l}
\text { - voice } \\
+ \text { back } \\
+ \text { high } \\
+ \text { stop }
\end{array}\right] \longrightarrow[+ \text { voice }] / \#-v\left\{\begin{array}{cc}
c \\
{\left[\begin{array}{cc}
- & \text { voice }]
\end{array}\right](i)} \\
{\left[\begin{array}{ll}
4 & 4
\end{array}\right](\text { (ii) }}
\end{array}\right.
$$

Rule \# 31 voices all $/ \mathrm{k} /$ o occuring in initial positions if the root begins with either a voiceless consonant or with a voiced alveolar fricative. This type of grammar 1.e. Natural Generative Grammar (N.G.G.) has formal complexities but reveals the actual linguistic realities. The realities of this rule are that the present day speakers of western dialects have more complex gramarye than their forefathers. This formal complexity predicts that for uniformity to be achieved the special markers on / / have to be erased. The NGG' prediction contradicte with TGG,'s prediction which claims that uniformity will be achieved by the less of the voicing rale (1.e. male 30)

The occurrence of $[k]$ before $/ \mathbb{/}$ in eastern dialects shows that the special markers that were placed on / / / were lost thus treating it like any other voiced consonant. Notethat it is not the lose of the voicing rule the took place. This to us is a good proof that $/ 0 /$ is not the underlying sound of $/ \mathrm{d} /$. The realities of this change is that NGO had the correct prediction which proves that formal elegance and right prediction do not go together.

The eastern dialects have gone back to the original uniformity of Dahl's law while the western dialects keep

#### Abstract

the violation intact. Our interests in these dicferences should be to trace the braking point between the two dialect groups. These differences can be formalised as Lollows:-

32. Stages E.dialects W. dialecte

| 2. | $C V+C V$ | $C V+C V$ |
| :--- | :--- | :--- |
| Volce | $+\quad+$ | + |

3. 

$C V+C V \quad C \quad V+C \quad V$

Poicen

In stage 1 Dahl's law was uniform but at stage 2 certaia change occurred that led to the voicing of the initial consonant of the root. At this point Dahl's law was violated. Sromiters of eastern dialects reanalyzed their Dahl's law and detoiced the consonant in the prefix position. The epeakers of weatern dialects did not ranalyze this rule and the violacion was made a permanent reality. As a result of the fadiure to reanalyee this rule wostern dielects have a more complex gramear than their eastera noighbours. This complexity should be revealed in our grameas and any theory that allows us to write a uniform granmar for the whole region should be questioned.

#### Abstract

The next question that we ought to ask ourselves is

What the motivations for this law are. Many ilaguists have the discussed law and have all agroed that this 1 a reve of regreasive roice diseiallation. Thej have not however diecussed the motirations bohind it. To ns this rale soenc to be explainable in teres of the inertia of human vocel organs.

In these dialecte it ceens that human vocal organs are greatly disturbed whor called upon to produce voiced and Soiceless sounds in rapid auccession. This may not be true of all human languages but we note that different languages have differant constraints, on what sounds will occur in a given sequence. In the dialects of S. Mt. Kenya It seens that a sequence of two syllables that begin Wth voicelese consonants is undersired. This explaine why nany borrowed words have their sound structures modilied ••8•
33. K1swahili

akeka
S. Mt. Kenya

Gl088
at (1)00r)

Faced by an undersired sequences of sounds the rocal organs have a numver of options to choose frog. The

#### Abstract

radical option is to throw out sone of the sounds 1.0. hyplology. Other options include aselvilation, metathesis. dissimilation etc. All these processes can be used to maximise the ease of production of speech sounds. These strategies, also, help to maximise the communicative role of human languages.

In these dialects the ain of Dahl's law 23 to reduce, to the minimum, the number of alternations. The surface forme Indicate that sequence of voiced sound e is more accel table than any other sequence. It can be claimed that vat the Law aline at is to make sure that no two adjacent syllables are allowed to begin with voiceless consonants. This can be confirmed by looking at the inllcwing example o.

34. underlying (1) kookama/ (2) ko-ruta/ (3) /kotaratata/

It is obvious frow the above analysis that where a
voiced syllable intervener no change ia needed. Since no examples of two adjacent syllables can be found to disaprove this claim wo are bound to conclude that the syllable boundary is crucial to the application of Dahl' law (cf. 4.1 .1. ) The adjacent syllable conetradet explains why / koruta/ has not been changed to \{orrit)\}

Constraints on the structure of adjacent syllables are not limited to the feature voice nor are they limited to bantu languages. We find similar examples that affect other features in other language groups. The example that most closely resembles Dahl's lav is Grassman'e law in Greek and Sanskrit. This is a law of diaspiration which can be stated as 'Whenever two aspirated sounds occur in two adjacent syllables, diaspirate the first one.' The aspirated sounds of these languages include:- /bl/. /th/ /dh/etce The diaspiration rule disallows any occurence of these sounds in two adjacent syllables. In features the rule can be formulated as:-
35.
 $\left[\begin{array}{l}\text { asp] }\end{array}\right]$

Rule 35 generates the following surface forms
36. Greek
/the/ 'put' /aha/ 'put'
S.D. /thi-the-wi/ /dha-dha-mi/
asp. + - + - - + + - -
SC.[titheai]'I put' [dadhami]'I put.'
asp. - - + - -

The similarities between the two laws is revealed by the surface forme which have no rapid succession of the undersized features. It is clear from these two laws that production of different sounds in raped succession is $n$
serious problem. Whether the problem is the keeping of the sounds distinct or in the articulation, is not known at this stage
4.1.5.2. Vovel diesiailation

#### Abstract

As defined in 4.1.5.1. disainilation is a procese bj wich sounds become wore differentiated. The motivationc for dissimilation have been said to be both concoptual and articulatory. The firat involvee the offorts of a speaker to aake two sounds more distinct while the seoond involves his inability to produce two sinilar sounds in a sequence. These motivatione contradict the reasons for assimilation - which ain at making the sounds more alike. One important fact about rules of assinilation and those of dissimilation $i s$ that none of them is univeres to ell languages.

One language or group of languages allows given sequence of sounds, e.g. voiceless sounds which is disallowed by enother group or language. Another language allows a given clustering of sounds that may be disallowed by other languages. We cannot therefore talk of any universal rule of neural ease, concoptual ease or articulatory ase without findias some linguiatic data to contradict our claims. These contradictions reveal the varying complexities of bunan languages. Sow of these complexities differ from language to language and cannot be accounted for in linguistic
universale. Thej have to be accounted for on language specific basis.

In the dialects of S. Mt. Kenye we find processes that cannot be accounted for in terms of regional universala. These have to be explained on dialect specilic basis. One of these processes is the change of $/ \mathrm{a} /$ to [i]after [J] that is generated from $/ a+u /$. This is an interesting case of rovel diseimilation because it changes a dorived forn. An earlier rule generates'[गu] from/au/ but this later rule changes [Ju] to [Ji] which on the face of it seems more complex than $u$.

At first sight [Ju]looks like an easier sequence of vowels to pronounce than au because of the difference in boight and the point of articulation of these two underiying vowels. The first onc i.e. (a) is a low nonback vowel and the second one is high back rowel. The change into u makes the two vowels similar by changing the first one to a back position. The two are now nearer to each other than their input.

On the surface on looks eney but when ve consider the parts of the tongue used in the production of these two rowels we find that this sequence creates certain probleas. The probleas include articulation of [J] and [a] in a sequence. Note that [ 2 ] is produced by the back of the tongue at a low poaition but [ © ] requires that the back of the tongue be raised to high poaition. Thoir differemce
in height deands that the back of the tonge shifta from a very law to a vory high position within a very short tiae (almost the same time). This type of shift seen most difficult hence the dissimilation of $/ \mathrm{a} / \mathrm{from} / \mathrm{J} /$ to make their production easy.

With the change of $[\partial u]$ to $[J i]$ the whole picture is changed drastically. [S] remains as back, mid low vowel while /u/ changes to a front, hifi vowel. The first is produced by the øover ont of the tack portion of the tongre and the second is produced by the movement of the front portion of the tongue. The two vowels hnve no direct interference because in producing[J]the back portion of the tongue has nothing to do with the tip of the tongue. In other words the tip of the tongue could be raised while the back of the tongue remained low. Here diesiailation has a simplificatcry role.

With the above discussions it should now be easy to see the processes t work. The following examples aro from wostern dialects where the rule operates:-

| 37. Onderlying | Assimilation | Digesiallation | Glose |
| :---: | :---: | :---: | :---: |
|  | (a) | , (b) |  |
| /a-a-ur-a/ | - jsura | 2ira ho | has bled |
| /a-ug-i/ | - Jugi | jigi lea | - 5 |
| / a - 10 m i/ | - こ1a! | jei out | 80058 |
| /a-un-i/ | - 2 uni | jini 'b | ake-s' |

To my knowledge no dialect ever uses forms in (a). We have the dialects using either (b) or surfacing the form in
their underlying forme. The Enstern dialecte surface
underlying forms while Western dialects use forms in (b) The two groups of dialects have generalized different forms. In Eastern dialects one never hears (b) forme while in Western dialects the surfacing of the underlying forms in the same form is more unusual than usual (cf. 4.1.4.)

To account for the surfacing of (b) forms in Western dialects wo need two rules. These are 38 and 39.
38. $V$

This rule generates forme in (a) that nobody pronounces. Now we need rule 39.
39. V

$$
\left[\begin{array}{l}
\mathrm{V} \\
+ \text { high } \\
+ \text { back }
\end{array}\right] \longrightarrow[\text { - back }] \quad\left[\begin{array}{c}
V \\
+ \text { bidlor } \\
+ \text { back }
\end{array}\right] \text { [ }
$$

This rule changes all forms in (a) to those of (b). No extrinsic order is needed for these two rules.

Another rule that is dissimilatory is that of glide formation. This rule changes front vowels $/ 1 /$ and $/ 0 /$ to $/ \mathrm{J} /$ if they occur before nonfront vowels. It also changes /o /into $[W]$ if it occurs before Lonhigh vowels. The diseimilatory nature of this rule is seen in the switching of features from [ + Voc. $]$ to $[-V O C$.$] when the following$
sound is vocalic. This switching of features must be sean as a strategy to change structures frow /vv/ to CV

The case of $/ 0 /$ changing into $[W]$ when it occurs before nonhigh vowels has two aspects of dissimilation These are the changing of a vocalic segment into a nonvocalic one and becoming higher than the neighbouring vowels. Note, for example, that by changing /O/ to [ [ Then followed by $/ 3 /$ makes these sounds become more differentiated than before the change.

The gliding rule occurs in its most general form in initial syllables. In this position all dialects glide but in final positions Western dialects are not known to glide. Glindigg is also blocked where the two vowels are Identical egg. $/ 0 /+10 / \rightarrow[0!]$.
4.2.1. Vowel harmony

Vowel harmony is one of the rare cases of distant assimilation i.e. assimilation involving sounds theft are not in contact. In our dialects the vowel in the verb root determines the vowel in the suffix. Among the two positions the root has morqfreedow than the suffix. In the root any of the seven vowels will occur but in the suffix only two vowels are allowed. Each of these two eufixx vowels i.0. [] and $[\varepsilon]$ takes a number of vowels, as indicated in 40

harmony in that the suffix vowels combine vowele that
have no common phonetic feature. Note that $[0]$ is the auffix rowel of $|\mathrm{i}|,|u|,|e|,|0|$ and $\mid$ aj. The first four of this Towels share common leature of highness whether widhigh or high. The fifth rowel is an extremely low vowel hence no phonetic grounds can be seen as the basis of the grouping. The other two vowels 1.e. $/ E \mid$ and $|\supset|$ take [ $[$ ] as their suffix vowel. These two can be said to have a common phonetic feature because they are both midlow.

The above examples lead to the following vowel classification:

| 41. Set I |  | Set II |  |
| :--- | :--- | :--- | :--- |
| High | 1 | u | - |
| nidhigh | 0 | 0 | - |
| nidlow | - | - |  |
| low | - |  |  |

The vowel harwony experienced here differs fron other vovel harmonies in that in other cases where vovel harmony Ls phonetically determined all front vowels go togetber while
all back vowels go together. Such a system exists in Turkish where front vowels $1, j, 0$, harmonise while back vowels, $u, a, o$ harmonise. It may also be possible to imagine a system in which high vowels harmonise with other high vowels and low vowels harmonise with low vowels. In -lither of these two cases such a harmony can easily be discussed in term of phonetic motivation.

Our examples frow $S$. Mt. Kenya lack any direct common basis especially in the five vowels of set $I$. I do not think that any linguists would want to account for this rife of harmony by positing acme abstract common feature. the suggest that wo look at it. as an unusual system and try to find wow best we can account for it. The best solution to us seems to be based on the concept of morpheme. This suggestion would list the applicative morphene as er- and then generate - $F$ by a rule. The rule would be as formulated in 42.

V
42. $/ 0 /[\varepsilon][+\operatorname{midlow}] \mathrm{C}]$ [suffix]
Rule 3 will only change $/ 0 /$ to [C] when the last vowel of the verb root is / $/$ or / / / which are the only aid low vowels in our chart.

Our vowel harmony rule does not need any justification for the grouping of the five vowels in one set. This approach
is justifiable in that the rule is not wholly phonological but is a morphophonological. Its reference to the sulfix meane that the rule is more than a phonological rule. We also have examples from other languages e.g. Kisvahili. In Kiswahili /i/, / / and /a/ take[1] as their suffixal rowel while $/ \varepsilon /$ and $/ J /$ take $[\varepsilon]$.

The Kiswabili harmony has been discuseed both formally (e.g. in classes) and informally. Some people use features such as [+ extreme] in order to lind a comon feature tor /i/, /u/ and /a/. Those three vowels will be marked as [+ extreme] which means that $/ 1 /$ and $/ u /$ are extome in being high while/a/ is extreme in being low. This argument leads to the following chart:-
43.

|  | $i$ | $u$ | $e$ | $\partial$ | $a$ |
| :--- | :--- | :--- | :--- | :--- | :--- |
| High | + | + | - | - | - |
| aid | - | - | + | + | - |
| back | - | + | - | + | $-(+)$ |
| extreme | + | + | - | - | + |

The feature extreme has not to ay knowledge been phonetically justified. It vould seen therefore that no phonetic feature exists to justify the phonetic classification of $/ 1 / \mathrm{h} /$ and /a/ into one set. As such one wonders if this is not another trick to account for the unknown.

We have yot another factor to support this morphene
theory. The factor id that in the same dislests there are other suffixes that do not attract the rule of vowel harmont. One of these morphemes is the consitive i.e. -idiThis morpheme never changes its form in any envifonments e.g.

|  | underlying | surface (N. dialect) | Gloss |
| :---: | :---: | :---: | :---: |
| 1 | /in-idi-a/ | inidia | canse to sing |
| 11 | /ug-180-a/ | ugidia | cause to say |
| iii | /omb-idia / | ombidia | cause to mould |
| iv | /et-idi-a/ | -tidia | cauce to call |
| V | /ken-idia | kenidia | cause to be happy |
| Fi | /rob-idi-a/ | ragidia | cause to bewitch. |

Here we do not get "renedia or "ryefia, for 44 (v) and 44 (vi) respectivoly, the forme that a trully phonologionl rele vould generate. This to us is a good proof that the eype of hamony that ve have here $i s$ not phosologically motivated.

The claim that synchronically the harmony rule is not phonologically notivated should not be taken as denial of its diachronic status. The division of the vowsls into tiva sets suggests that there may have been a historical rule that was phonologically motivatoc. The harmoniaing vovels any have been $2 l l$ high or all low. The first + group of $/ 1 / / 0 / / u / / 0 /$ may have taken $[0]$ as their suffixal rowal while $/ \varepsilon / / \partial /$ took $[\varepsilon]$. The third group may have been that of $/ \mathrm{a} /$ alone. Since $/ a /$ does not, phonetically, belong
to any of the two groups it may have been left on its own.

What is likely to have happened is that the suffixing of /a/ roots with [ ] was based on derivational morphology rather than on phonetic features. These /a/ roots were therefore marked for [ ] suffix and the marking remained intact. This claim may sound strange but there are many strange things in human beings and in their languages.

The time factor is also doubtful especially in view of the fact that other related languages have equally intriguing rules. It may have been feature of cose proto-language from which both Kiswahili and these dialecte originated. Whatever its source may have been the rule must have come into these languages at a very early date.

Before we conclude we should point out that this mule is both morphological and phonological. As shown in rule i,? the changed vowel is a suffix but the eavirorment in whicis it changes do not refer to any morphological information. For this reason the rule can be discussed in oither morphological or phonological sections. Since it must be in one section and not in two sections we have chosen to discuss it under phonological section.

In conclusion it is important to point out that this rule has no sigaificance in dialect clasaification. The only reason for its discussion in this study is due to the writer's comaitment to discuss all major phonological and morphological
processes of these dialects. The rule can only be used as one example of the common processes in all these dialects. It therefore helps use to put these dialects in one group.

### 4.3.1. Deletion

Deletion can be generally viewed as an end result of a weakening process. This is especially true where deletion follows assimilation. In such cases one can always show the weakening process that precedes deletion. There may, however, be cases where deletion has taken place without any evidence of weakening. Such cases are usually governed by syllable structure constraints (hence S.S.0.). Under such conditions clusters may be reduced 1 row / SC (c) VCr/ to C (c) VCV without prior wakening of the deleted sounds.

There may be other weakening cases that on the surface look like cases of strengthening. I magine ace of a liquid and a stop changing into a sequence of two stops 1.e. IC $\rightarrow$ CC. If one of the derived sound e drops out one might be tempted to think that deletion was preceded by strengthening. Even wen the two derived stops are retained, on the surface, wo have to treat this as weakening process. Note that even though the surface segment is stronger than its underlying segment its surface features are redundant.

Hooper (1973) gives examples of what she calls context-sencitive weakening. She gives the following examples (which are reproduced for clarification) pros Spanish:-

| 45. /verde/ | $\rightarrow$ rede [bode] 'green' |
| ---: | :--- |
| /carga/ | $\rightarrow$ cagga [Gaga] 'charge' otc. |

These examples show quite clearly that the derived sounds have lost their identity. I do not think that any linguist would want to call this a case of consonantal strengthenir.g I therefore agree with her that this is a process of context-sensitive weakening.
4.3.2. Nasal deletion

In Southern Mt. Kenya we have both nasal deletion and nasal reduction. The first occurs in initial positions when the following segment is a voiced consonant and the second affects medial homorganic nasals. The first of these two rules must be preceded by the rule of voiced stop formation. The latter rule generates voiced stope from voiceless consonants and voiced continuagje. The nasal deletion rule can be synchronically formulated as in 46.
46. C

$$
\left[\begin{array}{c}
c \\
{[+ \text { nasal }]}
\end{array} \rightarrow \sigma / /-\left[\begin{array}{c}
+ \text { stop } \\
+ \text { voice }
\end{array}\right]\right.
$$

This rule operates anytime its $S . D$, is net 1.0. in the Western dialecte.

As stated above rule. 46 wast be preceded by the voiced stop formation which is formulated as in 47.

Rule 47 is made of two different phonological processes. These are the weakening of voiceless consonants and the strengthening of voiced continuants. The two processes have different liaitatione depending on the dialect under discussion. To exemplify this we have the following examples:-

48 underlying: stop form. ki - KG -West- GloBe

(For the surfacing of $b, d, j$ and $g$ in western dialects see chapter 3).

Looking at the above surface forms one can easily see Why, in a given type of a grammar, nasal deletion should come after voiced stop formation. If nasal deletion was allowed to operate before the consonantal changes have taker. place we would get some ungrammatical surface forms. Of cause this problem could be easily overcome by adding more lectures to the rule. This has been done in this study. The problem would have arisen if less features were used in male 46.

In the western dialects the nasals are also deleted before / $/$ / This sound does not require the nasal because it is always voiced. We should therefore not worry about it in our rules. The rule may, hoverer, be made more general by letting it delete any initial nasal that occurs before a voiced consonant. In order to make this rule more general we need to reformulate it as in 49.
49. C

As shown in the above examples this rule will be limited to western dialects. These are the only dialects that delete initial nasals after the voicing of the consonants. In these dialects rule 49 can be shown to be generalization of an earlier one. The earlier rule deleted nasals when they occured in initial positions before/ and moo.

Among the two sounds the deletion of initial aasals before $\mathrm{h} /$ must be historically ordered before its deletion before /\&/. Two reasons lead to this claim. The first reason is the lack of any traces of nasals before $\mathrm{h} /$ wile some dealects still keep nasals before $/ \mathbb{V}$. This tc us iaplies that the deletion of aasals before this glide occured earlier than their deletion before the alveclar fricative. The second reason is that all written materials show that aesals are disallowed before the gilde while some researches have revealed the presence of nasals before the fricative. Some of the written aterials were recorded at the beginning of this century which would mean that the initial nasal deletion may have began during the last century.

The motivation for the rule lies in the identity of the features (cf. Hinnsbusch 1973) ${ }^{6}$ The deletion is preceded by a $\quad$ zul of reciprocal assimilntion. Note that the consonant following the nasal will have assinilated to the nabals stopngss or fte voicenees and the nasal will have essimilated to the point of articuiation of the consonant before deletion takes place. as a result of this reoiprecel assimilation the two consonants will share more features in common than their input.

When the reciprocal rule has operated many foatures will be redundant in that they are shared by the two sounds. Since the initial consonant has elready undergone sowe changes the deletion of the nasal vould not lead to any loss

#### Abstract

of information. Retaining the two sounds looks like double arising of the sase fonturea. To avoid this double marking one sound is dropped.

#### Abstract

Another possible couse of the deletion is the lack of contrast between roiced stops and roiced iricatives. In these dialecta the contrasts exist between prenasalized consonants and roicod continuants i.e. $\mathrm{ab} / \mathrm{B} ; \mathrm{nd} / \mathrm{r}$ g gs/bi $\mathrm{mb} / \mathrm{\nabla}$ or $\mathrm{mv} / \mathrm{T}$. There exists no contrast between [mb] and $[b]$ etc. This means that the reduction of a prenasalized consonant to an (simple) oral stop would create no serious perceptuel problen.

Discussions and examples given above confism what we said earlier about the operation of phonological rules. (Changes shown in 47 would not have been posaible if the morphophoneaic $\{n\} h_{a d}$ not been in the words. This is a further proof thret all morphemes have to be conbined into words before phonological rules begin to operate (cf. Hooper 1974). One might even go further and state that phonological rules should apply on words and not on smaller units.

The role of nasal deletion rule and other related rules in dialect classilication is self explanatory. The Eastern dialects have no nasal deletion. They are grouped together by lack of this rule but have their own internal divisions. The interanl devision in Eastern dialects
classifies Gichugu - Ndia region as one subgroup opposed to Mbeere - Embe subgroup. The dividing line is River Rupingaci. The dialects west of this river i.e. Gichugu and Ndia have a general rule of strengthening of all the continuants including /Ad. The subgroup lying to the east of Rupingaci fails to strengthen all cuntinuant. Tine: variations are shown in $50(m a n)$

50

Whether Gichugu-KiNdia group will have nasal deletion as in Western dialects is not jet entablished. The important thing about the above foras is that they have established a different grouping just like the metathesis dide

The dialect boundaries ectablished by the above rule should not be taken as indication that Kimbu and Kimbeere are identical in their surface forms. As we pointed out In 3.1.1. Kigabu has [mv] from/n-V/while KiMbeere has [nb] for the same underlying forms. What we should note is that the two dialects agree in number of ways e.g. generation of [ $p$ d $\mathrm{from} / \mathrm{n}-\mathrm{d} / \mathrm{but}$ disagree in a number of rales. ${ }^{3} \mathrm{he}$ [ nd ]of KiEmbu - Kimbeere group separates this subgroup
frow their neighbours i.e. Gichugu and Nadia who have [nd] for the same underlying form.

As we mentioned at the beginning of this section we have both nasal deletion and nasal reduction. The latter is most evident in Western dialects where medial clusters are reduced to almost single consonants. In sone areas ecg. KiMathira dialect there is a rule of vowel nasalization. The rule operates when vowels occur before nasal clusters or what is usually called prenasalized consonants. This rule is formulated as in 51.
51. $v \rightarrow[+$ nasal $] /-\left[n_{c}\right]$

For KiMathira speakers this rule is general but for other areas the rule is generally replaced by rule 52.
52. $\nabla \rightarrow[$ +long $] /-\left[\mathrm{n}_{\mathrm{C}}\right]$

The difference between rules 51 and 52 is that while rule 52 does not, always, include nasalization the forme derived by rule 51 are always long. On regional basis rule 52 is more general than rule 51. Wo cannot however do without rule 51 because rule 52 does not include nasalization. The differences between these two rules are revealed in \# 53.

| 53. underlying | KiMathira | S. dialect | Gl08: |
| :---: | :---: | :---: | :---: |
| n-kanga | $\frac{\grave{a}}{\text { e:ggá }}$ | ga: yga | gunea fowl |
| £̇anwa | $1 \text { zEnwe }$ | idanwa | axe |
| mungu | ※uiggú | -ù geu | tumel |
| dambera | dàinbéra | dambera | swis |
| kanjore | kaifjóre | ka:pfore | Kanjuri |
| ne-n-kanga | $\text { nढें gहä: } \ddagger \mathrm{E}^{a}$ | $\text { ne: } 98 a!38 \text { a }$ | It is a fowl |
| m de-agoro | mesaiggoro | Cclaiggoro | an old tablo |

Lengthening is liaited to positions before voiced stops (cf. 3.3.2.) In Mathira these nasal vowele are so distinct from oral ones that they should be shown in our gramar.

One posible cause of this might have been the
influence of a nasal which has been lost but whose foaturee vere assimilated by the vowel before it was deleted. -his is the ovidence we get when we compare the following examplesi-

| 54. | Gie chugu | Mathixa | N. dialect | Bource | Glons |
| :---: | :---: | :---: | :---: | :---: | :---: |
|  | $\frac{\grave{n}}{\mathrm{~m}} \mathrm{nd}$ | 立ว: ź | b:d | - $2-\mathrm{ad}$ | all c |
|  | so:ndé | mo: | eo:dó | -mos nde | pestl |
|  | jد̀:ndí | $\frac{\grave{j}}{j} \mathrm{E}$ | jo:er | - $0-3-\mathrm{n}$ | 0110 |

In these examples RiMathira's naslized vowels
correspond to long vowels of Northern dialect. They also
correspond to KiGichugu's nasals. Frow the above comparisons it is obvious that KiMathira's nasel vowels are derived from nasals and not an independent innovation. The above nasal
clusters must have beon : feature of proto - S. Mt. Konya.

### 4.3.3. Glide jeletion

In the preceding section we have clained that for nasal deletion to take place we need certain feature identities. We noted that these included identity in point of articulation, identity in roice and in stopases. In this seotion we shall examine the conditions under which a palatal glide (i.e.[d]) is doleted.

In Southern Mt. Kenya a palatel glide is deleted if it occurs before a front high vowel. In features the rule is us follows:-
55. $\left[\begin{array}{l}- \text { cons. } \\ - \text { voc. } \\ + \text { high }\end{array}\right] \quad \rightarrow \quad \phi \quad /-\left[\begin{array}{c}v \\ \text { bi gh } \\ \text { back }\end{array}\right]$

The abote environsent is created by the addicg of the nominalizing suffix $\{1\}$ to the verb roots. When such verb roots end in palatal glide the glide is deleted. The root has, also, to be prefixed by other morphenes which are not relovant to our discussion. The operation of rule 55is exenplified below:-
56.

$$
\begin{aligned}
& \text { n-8aj - } 1 \\
& \text { आO-hつj-i } \\
& \text { Eohó begger cl. } 1
\end{aligned}
$$

56

| $k e-21-1$ | kepi | lifter cl. 7 |
| :--- | :--- | :--- |
| mo-koj-1 | nokó | etarter cl. 1 |

These examples differ from the following fores which are derived from the same roots.
57. [8ajá] divide gajand the dividing

| $[$ [j̀jà beg, prey | ibjjà | pray |
| :--- | :--- | :--- | :--- |
| [jjá ] lift | jวjánj̀ | lifting of each |

other
[kojak] start (song) gojanerj starting for each
other.

A comparison between examples in 56 and those in 57
lead us to the conclusion that glide deletion is based on our earlier claim of feature identity. In these examples we see that deletion is allowed in 56 because [ j ] and [1] a share a number of common features while in 57 deletion is blocked because [J] and [a] do not share many common features. For further discussions on feature identity read Hinnebusch (1973).

It may look strange to some that wo have glide insertion in one section and glide deletion in another section. Such people would, probably, try to posit the a high vowel instead of a glide so as to avoir the glide deletion rule. Such an approach would not be allowed in
the theory used in this study.

The theory uaed in this study would choose the
glide because it has more freedon of occurence than the vowel. It is also true that this vowel carries morphologi, ? and not phonological information. To change it into a glide in all cases except in nouns would be a strange thing. Such a rule would not be a phonclogical one. Another reason why this vowel cannot be posited as the root sound is that of historical changes. In chapter 3 ve gave examples of - B changing to / $\mathrm{J} / \mathrm{in}$ certain words. If we posited/i/ as the root sound for the above roots we wold be claining that this bilabial fricative changed into a high front vowol in certain words. This clain is not supported by an evidence. For these reasons ve reject the poaiting of the vowel as the root sound in the above examples.

Our glide deletion rule works against the preferred syllable structure. It changes structures fron/cvco/to[COU] Bere we have a case of a phonotically proforred etruoture working against another phonetically preferred structure. - 1

This is a caselthe conilicting constraints that wo ofton find in human languages.

In dialect classilication this rule has no internal relevance. It does not iivide our region into any baller divisions. Its role should be seen ae that of clateifying the whole region into one entity.

### 4.3.4. Liquid delotion

In Southern Mt. Keny dialecta ve have one phonemic 1iquid. This is $/ \mathrm{r} /$ which in some people's speeches Ilucturtes between $[r]$ and $[1]$. In these speakers efther of the two could be phonenic but for aajority of speakers the phoneme is $/ \mathrm{r} /$. This phonewe is realised as [1] when it occure before front vowels or in initial positions while F is realized before back rowels and in medial positions.

In this section we shall deal with liquid deletion. This rule deletes a liquide when it occurs after a formative boundary. In features the rule is formulated as in 58.
58. Liquid $\rightarrow \varnothing /+-V(+)$

The only examples available are those that generate a liquid from the mid-future tense marker i.e. re. Whether a aimilar situation would arise if the liquid came from another morpheme cannot be proved. It is assumed that the liquid will be deleted any time its structural description (SD) is met.

Another thing that we should point out is that there is another formative boundary that follows the vowel, in rule 58. Whether or not this second boundary has any role to play cannot be exemplified because ve have no examples of 11quid deletion before formative boundary. For this reason we shall assune that thic second boundary is not
important for the application of the liquid deletion rule.

#### Abstract

Before we give example for this rule we should note that this rule could be discussed under morphological changes. This reoults from its limitations to cortain morphemes only. It is hard to prove that the rule is not phonological because no liquids are found to occur before a formative boundary, on the surface. Due to this lack of certainity the rule hes been discussed under the phonologioel chapter. Its discusaion in this chapter implies an aseumption that all liquids will be deleted whenever they occur after a formative boundary.

Even if it was found out that the rule was liaited to a given set of morphemes it would still be discussed under either phorological or morphological chapters but not in both. It is for this reason that we have cnosen to put it in this chapter. We do however agree that there may be equally good reasons to discuss it under morphology.

Having decided to discuss this rule under phonology we should now go ahead and show how the rule operates. This will be shown by the following examples:-
59. undorlving 3 Nedialect S.dialect glose

| $/$ to + retdie | torèdio | twódi: | 'we ohall go' |
| :---: | :---: | :---: | :---: |
| /a+retkama/ | 'arókámà | Ékama | He will milk' |
| /rotretrea/ | nororaa | mwóreà | you(pl.) will |

These structures are not found in KlEabu, KiMbeere and many KiGichugu speakers. The lack of these forms comes from the replacement of $\{r e\}$ tense marker with $\{k a\}$ tense marker. In Nadia many speakers have forms that are identical to the structures found in the Northern dialect. Since reduction is limited to the Southern dialect this rule is important in dialect classification.

Rule 58 is not motivated by the sane constraints a preferred syllable structure. The result of rule 58 is changed by syllable structure constraints. Note that $/ 0$ ! is glided after liquid deletion thus placing/o/ and $/ e /$ in one syllable. It may be that this reduction of \{re\} t e n s e ~ i s ~ related to its disappearance in Eastern dialects (cf. chapt. 2)

In rule. 58 we have used a formative boundary and not a word boundary because we feel that word boundaries have nothing to do with this rule. To prove this point compare the following structures. (ae 60).

From these examples wo learn that in word initial positions the liquid is not deleted as it vas ie rule 58. The initial liquids tend to be generalised rather than deleted. Note, for example, that Ki. Babe has the initial liquids in all the above examples. In other dialects the liquid is deleted if the root begins in a consonant. The change 1 rom */re/ to [ 0 ] can also be treated as a diachronic change. (see 61)

## underlying： <br> KiMbeere <br> K1Embu

／retgina／
$/ r e+n \quad n /$
$/$ ret ru／
／rat ga／
／re＋nge／
－：$n 8^{\circ}$
－${ }^{-1 m a}$
enenc
rejru
ressa
1Jว
1〕と名a

10：g8e

$$
\text { 61. } \cdot|\mathrm{re}|>10 / \quad \rightarrow
$$

Rule 61 presupposes a restructuring of the class marker from $\{r e\}$ to $\{e\}$ in the cause of history. This is the only approach that can explain why the liquid is deleted before consonants ie. changing/CVCV/ to[VCV]. This to is seems more diachronic than synchronic. For more details on the morphemes see 2.2.1.3.

After the change from $/$ re/ to / / occered another change took place in Western dialects. This new change raised e to 1 whoa this morpheme occured before a consonant 1.e.
62. $\{\cdot\} \mathrm{cl} .5 \rightarrow[1] / \#-\left[{ }^{c}\right]$

The marking of /e/ as a morpheme is important because we have other identical vowels that do not change. For this reason /e/ should not only be marked as a morpheme but also as cl. 5 morpheme. The inclusion of norphophozemic features means that the rule is not wholly phonological? but morphophonological.

The rules discussed in this section have separated our dialects on different lines. The [re ]generalization has separated KiEmbu from all the rest and the raising rule has separated $W$. dialects from the rest of the dialects.
4.4.1. Vowel lengthening

Vowels are always lengthened when they occur before prenasalised consonants. For those speakers that dave dropped the nasal elements in such environment lentheaing met be seen as taking place before voiced stops. Such would be the ease in a number of speakers of both Northern and Southern dialects.

The vowel lengthening discussed here should not be confused with phonemic long vowels. The two types of vowels are quite different. Phonemically long vowels have as much freedom of distribution as short vowels. The derived long vowels, on the other hand, are limited to a number of environments. The first environment is the one mentioned above and which could be formulated as follows:-
$63 \mathrm{~V}-[+$ length $] /-\left[^{n} \mathrm{C}\right]$
This rule generates the following forme.

Some speakers in Western dialects will produce the above structures without the nasals. For these speakers the vowel lengthening will require a voiced stop and not a prenasalised consonant.

Except for the nasal reduction that occurs in the Western dialects this rule has no effect on dialect classification. We do however have another vowel lengthening rule that has effect on dialect divisions. This is the rule that lengthens the first vowel of the perfect tense $\{0 t \varepsilon\}$. This rule cannot be formulated in features because there are other occurences of $/ 0 /$ before $[t]$ that are not lengthened. For this reason the rule must be formulated as:-
65. $/ e / \rightarrow[+$ length $] /-[t \varepsilon]$.

Rule 65 operates in Southern dialects and the southern edges of Northern dialect only (see map ). With rule 65 we have the following forms:-
66.

| /ne-a-ok-etc/ nejke:tc | njokete | He has come |
| :--- | :--- | :--- | :--- |
| /ma-ti-etc/ madieste | madietc | They have gone |
| /ne-ma-tar-etc/ nematareitc nemataretc They have counted |  |  |

In order to understand the nomphonological nature of the above rule compare the forms in 65 with those in 67 .

These examples and especially $4^{\prime}$ i) show that $/ e /$ does not lengthen before any $[-+\varepsilon]$. It has to be a given typ of /e/ in order to lengthen. Since no phonetic arguments are available for this rule we have to simply put it down as it is without any phonological explanations.

As alternative to this anlysis could be found in underlying representations. If we take that different dialects have different underlying representations we shall not need to have this arbitrary rule. This alternative ie discussed in chapter 5 (5.3). In that chapter the reasons for different underlying representations have been given.

## Footnotes to Chapter 4

1. Kisseberth (1969) discusses the Iawelmani openthesis. He showed that by positing the echo verbs as.CCVC it was easy to apply (and justify) vowel epenthesis to break up the clusters. Positing of these verbs as CVC or CVCC would lead to dificulties because the language had other similar clusters that did not actract epenthesis. Le compared the following examples:
(i) /ili: hin/ 'found'
(i) /xil/ 'tangle'
(ii) /hyo:hin/ 'named'
(ii) 711k/ 'sing.'

Morphewes in la attracted openthesis but those of ib did not. The examples in la ourfaced as (?11e:hin) and hojo:hin reopectively. Kisseberth concludes that what is restricted is the initiel consonant clusters. To get rid of such clusters a given vowel has to be inserted. This claim is vell founded especially when we compare this with wat happens in other languages (cf. footnote 3.)
2. Byarushengo (1973) stated that the Haya'e palatalization and affrication rules vere applied differently by different age groups. He found that one age group applied the two rules on $/ \mathrm{k} /$ and $/ \mathrm{g} /$ while another group applied palatalization only. The group that

```
palatalized but never affricated the velars ended
with (k) and (g) while the other group ended witn
palatal affricates.
```

3. Hooper (1973), 'Aspects of Natural Generative Phonology,' proved, quite convincingly that the Spanish epanthetic rule was needed to break certain consonantal clusters. Any Spanish word that hae initial clusters are subject to an epenthetical rule that breaks structures frow CCV to VC \& CV These words are borrowed from other languages that do allow the type of clusters that Spanish disallows. The borrowed words include.
```
esnob 'snob'
esmoking 'turedo, (amoking jacket)
e日lavo 'slaw'
```

After the epenthesis a syllable boundary is inserted between /a/ and the following c. This is a clear case of the constraints imposed of syllable structures. Note that these Spanish examples correspond to the Yavelmani olusters given in footnote 1.
4. One of my informants cited an examples of the types of insults that young people or speakers of small dialects receive from those who think that the dialect (s) is not good enough. she recalled an
experience with her elder brother in Nairobi. She had spoken in her Mathira dialect and used certain local morphemes and pronaunciation. One of the morphenes used was $\{a\}$ for cl. 2 objective marker. Her brother asked her, 'Whea will you grow up to speak as an adult?'

Her brother expected her to say [3] which is the written $x p r y$ but she did not. Other reprimands and corrections include the violation of Dahl's law. When children fail to violate this rule they are alwaye corrected by the adults. These children first learn to place $[k]$ before [d]e.g. kidinii 'a man's name' kedenji) 'a man's name' etc. The adults tell then that they should be aaying Gadingi and Gefdenji. These are the standara norme.
5. Vennemann (1973) 'phonological concreteness in Natural Generative Plonolog. In this article Vennomann sets out $c$ rtain pranciples that mre supposed to constrain our chonological theory. One of these principles is the, 'Strong Naturalness Condition, ' which requires that the underlying representatione of non-alternatiog morpinemes be identical to their phonetic forms. For the alternating morphemes the underlying representations should identical to one of the surface forms. Thie constraint rules out any abstract representatione.
6. Hinnebasch (1973)

Augues that for - /ma/ syncopation to take place in Kenjan Coastal languages the two segments have to agree 'positively', in reepect to cover feature [+ labiality]. When such an agreenent has been achieved there is a tendancy for one of the segeents to delete. This happens because the features of the two segments are redundant.

## CHAPTER 5

5.0. Underlyins and surface forme

In chapters two, three and four we dealt with dialectal differences that exist in morpholexical and phonological etructuros of the dialects of S. Mt. Kenya. In this chapter we shall focus our attention on the relationship between underlying and surface representation. The purpose for this analysis will be to show when and where restructuring occurs.

Our discussions on restructuring will be necessary in justifying whether or not all the dialects have the same underlying forms for the given morphemes. Any theory of sound change that iails to show restracturing does not reveal the actual process of change. One of the reasolle for such failures is rule ordering in syfarom: gramara. It will tberefore be aecessary to relate rule ordering and restructuring in taje chapter.

In 4.1. we discussed a number of components in our Inguistic theory. These components will be oxamined in this chapter so as to reveel the componeats, if any, "nhich all or some dialects have common underlying forms. We shall also be able to show clearly the components in which common underlying forme should be ruled out.

In cases where a common underlying form exists it will be necessary to show how the surface forms of differont dialects are generated. The generation of surface formb without mile ordering imposes a serious constraint on whe rules can do. For this reason the formulation of rules vill have to be examined and evaluated on the basis of what the rule predicts and whether the predicted change is a natural one. The test for the correctaess of the rules will, in this case, be based on the changes found in the dialects. In other words, do changes experienced in the dialects and the rules written agree? If they do not agree then the linguistic theory used in the writing of such a gramar should be rejected.

The above paragraph touches on two inportant aspects of sound change. These are rule interpretation and the diachronic sequence of the rules. These two aspects will be scrutinized in this chapter. In 5.3 .2 rules of each of the two linguistic theories discussed in this study will be interpreted and reason for or against the rules given.
5.1 The relevance of oroto-language.

A number of factors lead us to the conclusion that the dialects of S. Mt. Konya come from a common protolanguage. " These factors include mutual intelligibility between all the dialects, a very clear system of sound correspondences between the dialects and a very high percentage of common vocabulary. Mutual intelligibility
ray, of course, cone as result of constant interaction between two different dialects or languages. This heppeas When the two are adjacent to each other but this is not the case in S. Mt. Kenya.

In $S$. Mt. Kenya dialects that have no common boundary have not shown any problems of interaction. A comparison between KiMbeerg and KiMathira or between KiEmbu and Southern dialect shows that the major differences are in sounds and tones but not in lexical items. Speakere such two dialecte get along without any need for an interpreter. My om research is a clear indication of this mutual intelligibility. I conducted it in my dialect i.e. Northern dialect and nobody ever complained of not understanding ne.

Despite what has been said in the above parapraphs we would still insist that the reasons for claiming that there was a common proto-language should be based on all three factors listed above. All three given us firmer base for our claime. Thry also raduce the orobability of borrowing as a reason for tne present state of afairs.

### 5.2 Underlving lex-cal diflerences:

In 2.1 wo discussed and exemplified lexical differeaces between cur dialects of study. In this section we want to ask whether or not all these dialects have an identical underlying structure.

We take the vieu that a lexical item exists or does
not exist within a given dialect or gromp of dialects. If the lexical iten is not ueed in one dialect then it is not part of the lexical structure of that dialect. In S. Mt. Kenya we have worde that never surface in some parts -.g. the words for 'dog' is Kuró and totó, in castern dialects but ggui or ggite in western dialects. The lact two words are also found in eastern dialects but the reverse is not true. This to us means that the vords Kuro and totó do not exist in western dialects.

Other words could be given to show dialectal variation but we feel that a long list of words will be unnecessary. What is important is the claim we have already stated i.e. the lexical structure of a dialect consists of the words used by the speakers of that dialect. Any word that does not surface anywhere ioes not exist in that partichiar dialect.

For any linguist to claim that the word gaka' 'grandmother' exists in western dialects even though nobody uses it is to go too far. It is unjustifiable to posit such a word and then claim that it is lost by a given rule. If such claims were to be accepted in our linguist theories that would be denouncing innovation, borrowing and semantic shifts. These arealready established phenonena of linguistic changes.

Our claia that the dialects do not have a common lexical structure should not be taken as a refusal of a
comon origin for all these dialects. A given word could have been borrowed froa neighbouring language of one of the dialecte. It may have been a part of the proto lexical structure that is retained in one dialect or group of dialects but lost in other dialects. The change could also occur through semantic shifts. Inese dehenomena have to be taken into account when we discuse lexical etructare. For further lexical differencen see anpendix 3.
5.3 Morohological rerresentations:

The morphological structure of these dialectí reveal quite interesting differences and cimilarities. There ase those morphemes that come from different proto-roots and which are so far apart that nobody would want to relate them. The most interesting case is that of the locative marker. This morpheme is re in KiEmbu and Kimbeore, \{ino\} or $\{n i\}$ in other dialects. Among these three surface forms $\{r e\}$ and $\{i n e\}$ are the most common. The third i.e. \{ni\} occurs in Ngariama location of Kigichuge dialecte.

The surface realization of the locative morphenes are as follows:-

1. Kibmbu-Kimbeore The rest (except

## G108s

 Mgariana Location)| mogondasre | mogondaine | 'in the Shamba'. |
| :--- | :--- | :--- |
| gote:re | goteine | 'on the chair'. |
| nduka:re | ndukaine | 'at the shop'. |

From these examples it is clear that the Embu - Mbera morphene is not derived from the same source as the morphene for the other dialecta. Here we need not debate whether or not the two have a common origin. What we have to investigate is the origin of $\{r e\}$.

The source of $\{r e\} l o c a t i v e ~ i s ~ " r e ' v e r b ~ t o ~ b e ' . ~$ This $\{r e\} v e r b$ to be'is still found in these dialecte (cf. 2.2; 4.2.3). This morpheme was split (i.e. in KiEmbu and Ki-Mbeere) into two separate morphemes. One of the two morphems stood for the verb to be while the other becase locative. As shown in 2.2 .1 the verb to be morpheme was later reduced to $\{\in\}$ in both Ki-Embu and Ki-Mbeere but the locative was not. In Sourthern dialect \{re\}verb to béwas reduced in the same way as in these two dialects. All other dialects have retained tiae $\{r e\}$ 'verb to be'.

All other morphemes discussed in this study can be derived frow the same proto-form. One such morphenes is the plural suffix discussed in 2.2.1. We argued that this morpheme was $-n i$ in the proto-language. In western dialects this suffix has been reduced to $-i$ but the eastern dialects have kopt it unchanged. Before discussing the form of the present day plural enffix let us have
a look at other morphemes.
dowains restricted by the expansion of the domains of Other morpheses. Among the reduced morplsences we have \{re\}class 5 marker. In Kimbeere this his been reducel to\{ $\}$ but other dialects have not changed it. In 2.2.1. we gave examples of \{re\}future tense marker which has been replaced by $\{k a\}$ in eastern dialects.

In all these cases one can show that the different surface forms are diachronically derived from one coman proto-farm. Except thim comon origin the different dialectal forms do not always have a comon underlying form. There nay be some early generative gramarian (e.s. Chomeky and Halle 1968) who still bold that the surface differences are generated by phonological rules. This achoel of linguistice argues that underlying formese 'very resiatant to changes'. This was the group that M.Y. Chin and W.S.Y. Wang addressed when they said,

Current generative theory would have us belleve
that the phonological component of rules is in constant flux as time passes, but that the underlying foras remain relatively constant throughout the ages ... language 51 No. 2.

The two scholars contiaue to say,
The chrolonology implied by this view is implausible to say the least. language 51 No. §2\$.

With the above quotation in Eind one would find it
totally unacceptable to suggest that in Kimbeere we still have $\{r e\}$ as class 5 marker which, on the surface, changes
to $\{0\}$ in all environments. The same could be said of the plural suffix "ni in western dialects. In cases where an old morpheme has been reduced it is obvious that restructuring has taken place. The only reason why T.G.G. would insist on having an abstract form is becquse it has no mechanism to detect restructuring.
N.G.G. rejecte the positing of any form that never surfaces because it does not exist. The positing of an abstract form tends to mix the diachronic foras with synchronic ones. A more concrete approach reveals the synchronic reality and makes more accurate predictions. In a concrete approach complexities in synchronic gramare are formally revealed.

Before we conclude this section let us look at two more morphemes that T.G.G. might claim have common underlying forms in all the dialects. These two morphemes are the perfect tense morpheme etk and the morpheme for all - JtE. The first of these two nordheres surfaces as [e:tc] in Sourhtern dialect. In all other dialects it surfaces as [ot\&]. In 4.2 .5 we lenptaned /e/ by a phonological rule i.e. rule 75 (4.2.5).
is we stated in 4.2 .5 there is no rule that lengthens all $/ \mathrm{e} / \mathrm{s}$ before $[\mathrm{t}$ ]. To posit /e/ underlyingly and then change it to [e:] in one morpheme only is phonologically unmotivated. This amounte to neutralization of / / in one morpheme. Such a noutralization is in no way a
phonological rule. We must therefore reject rule 75 of chapter $4(4.2 .5)$ i.e.

$$
/ e / \rightarrow[+1 \text { eng,th }] /-[t \epsilon]
$$

This leaves no olber alternative except to posit
/e:tl/in S. dialect and/ete/ in other dialects.

Identical arguements are given for the * $2+\mathrm{E}$ 'ell'
worpheme. In Kifmbu and KiMbeere this morphome is 2pdi. in RiGichugu snde, KiMathira $\overline{5: Z \varepsilon}$ and other dialects have J:d\& For KiEmbu Kimbeere and KiMathira wo can have one common underlying form /วnde/. For Ndia, Northern and Southern dialects wo have a:de but for Gichure wo poait -nd $\varepsilon$ -

The reasons for positing gnd $\varepsilon$ in the three dialecte mentioned above are obvious. In these dialects the nasal is quite evident. In the other three dialecte no nasel is present. We cannot clain that leagthening is caused by the loss of the nasal because long vowels are phonealc in these dialects (cf. 3.2).

For Kigichugu the underlying form is not Pud $E$ but /-ndk. This happens to be the case because [J] can to replaced by other vowels if the clase changes e.g. unde 'all' cl. 14. For other dialects this will be wวple, wJ:2と or wa:de "all' (cl. 14). These surfice differences make it clear that Gichugu does not treat as part of the root. Note that all other dialecte
prefix this[J]with the class marker.

As with the perfect tense marker we cannot posit a single underlying form for all these dialects. What we need is a single proton form which in proto - S. Mt. Kenya must be and E. From this proto form we can generate the present dialectal forms through a sot of sound changes. To exemplify these changes we have the following rules:-
2. KiGichugu

$$
\left[\begin{array}{l}
C \\
+ \text { voice } \\
+ \text { cont. } \\
+ \text { cor. }
\end{array}\right]>[- \text { cont. }] /\left[\begin{array}{c}
C \\
{[+ \text { nasal }]}
\end{array}\right.
$$

3. KiMathira
$V>[$ +nasal $] /$

$$
\left[\begin{array}{c}
c \\
+ \text { nasal }] \\
+\operatorname{con} t \\
+\cos \cdot
\end{array}\right]
$$

4. C

$$
[+n a s a l]
$$

Rules 2,3 and 4 are enough to generate the surface forms of Gichugu and Mathira. Emu and Moeere need no rule. For Nadia, Northern and Sourthern dialects we have rule 5.

$$
\text { _ } \because 11
$$

5. c
$[$ +nasal $]$

$$
\left[\begin{array}{l}
+ \text { roico } \\
+ \text { cont. } \\
+ \text { cor. }
\end{array}\right]
$$

Note that in all the above four rules restructuring is claimed to have occurred. We do not, therofore, need any common underlying form for all the dialects. This is the only solution that will be allowed by a gramar that disallows abstract underlying forms.

In this case our theory posits one of the surface forms as the underlying forms and cannot deviate from the above claims. These claime are strong but their interpretations are testable within each dialect. The dielects that show no traces of nasals do not have thew underlyingly. Those that have them can be easily gezerated by the above rules.

With all the above examples anc discus6:0日B it is clem that not every mornheme ca: be generated frou a common synchronic underlying form. Some may be derived from common proto-forme but the same is not true synchronically. In short we reject the claim that $u$ underlying forms remain constant throughout the ages.
5.4 Proto sounds and the synchronic sounds:

In 3.1 we saw that proto S. Mt. Kenya bad fifteen consonants and two senivowels. This makes total of seventeen nonvocalis sounds. We then discussed the changes
that have led to the present sound differences between the dialects. At that point we did not ask ourselves whether the dialects have a common underlying sound structure or not. The purpose of this section is to ansver that question.

If we argue that these dialects have difforent underlyine structures we shall have to address ourbelves to a more serious question i.e. at what point did rentructuring occurf For those, if there are any, who would argue that these dialects have a common underlying sound structure the question of restructuring does not arise.

By invoking the Strong Naturalness Condition
(cf. 4.1.4) N.G.G. has rejected tae positine of a common underlying sound structure. Remeaber that this condition limits the underlying forms to one of the surface forms. If a dialect has no surface forms with a given sound then that sound is not a part of the sound structure of that dialect. As stated in the preceeding sections of this chapter this is formal way or establishing restructuriag in sound change.

The above paragraph has shown that N.G.G. does not accept a common underlying sound strecture for all the dialects. This is possible because this theory has a definite method of showiag where restructuring hee taken place. T.G.G. on the other hand recogaises this procese of sound change bet lacks enough constrainte to establish it. These differences between the two theories
have serious inplications in our analyees of the syahronie sound structures of S. Mt. Konya.
N.G.G. would posit different underlying form for different groups of sounds. Klzaby and Kimbeore wonld have the eame underlying sound atructure but difforons rules to generate surface forms (cf. chapter 4). Gicheru and Ndia would have a common underlying structure difforme frow that of KiEmbu and that of vestern dialecge. Yoseona dialects would have certain comon underlying forne an certain different foras. One such difforat form mould be the nasal element in *Jnde wich is still trocenbio in Kikathira but not in other vestern dialecte. Fhore would be different forms for $/ B /$ in Sonthen dialect ant /f/ in Mathira and Northern dislects.

The above discussion does not inply that these dinlodef will not have many cases of identical underlying farm. Such a claim would be wrong because many pounde are common to all the dialects. The paragraph eiaply meyn that looking across the board, one would find wore in common in each group of dialocts than in all dinlecte.

It is also important to state that the diseuselone this in_section have nothing to do with the diachroalc procers. Diechronically all these dialecta have the seme origin and each sound can be traced fron a comon proto source (cf. chapter 3). The present syater of sounds in the dialects are accounted for by a set of souad restructurita.

The claise made in this ectime ennnot be cormally - stablished by T.G.G. as exerplified by Chomsisy and Hallo (1968). T.G.G. (as in S.P.E.) is, mainly, interested in Formal elegance. This elegance obscures the complicatione that arise from sound changes. Until this theory establishes Pormal mechanism to deal with such things as restructuring we are bound to conclude that it does not correctly deal with aound changes.
5.5 The sequence of historical rules.

In 4.1 .4 we rejected the extrinsic orderarg of phonological rules in our syachronic grammars. In this section we shall discuss rule ordering in a diachront. persoective. The constrajat on extinsic orciering of ales is meant to disallow the positing of abstract forms in any synchronic gremoar. Consequently the constraint disallows absolute neutralization (cf. rule 30 in 4.1.5.1). These are necessary restrictions if our gramars are to account for the intuitions of native speakers.

The restrictions placed on synchronic granare cannot be applied on diachronic sound chamges. The two have quite different operations. In diachronic sound change analysis we are dealing with changes that heve , occurred in different stages. The different stages may have occurred at different poriods. One change mey be separated from the next one by a number of years. Sone changes may overlap thus blocking or accelerating each
other (Vang, 1969). Whore posible the changes can be ordered in a hietoricol sequace. This is different from extrinaic rule ordering.

To begin our discuseion let us look at the relationship between ${ }^{B}$ and ${ }^{\circ} P$. In 3.1 .2 ve argued that ${ }^{B}$ loss must have been historically ordered before P- lenition in all the four di..lects. It is also true that - /B/ loss was completed before P- lenition. Had this not been the case we would find many remnants of Burfacing in nonnasal environments. It should be remembered that in our discussions on these changes we did not have any exampis as of "B surfacing in nonasaal environments of any synchronic grammar. All the $/ B / E$ and $/ V / s$ that surface in the four dielects of Gichugu and Ndia and Enbu and Mbeere are derived from $P$. There is no overlapping between these two sounds except in nasal eavironments.

These four dialects seen to favour a procese that veakens the bilabial consonants. This process began with the loss of the bilabial fricative then there followed the lenition of the bilabial roiceless stop. In Gichugu and Ndia the lost fricative is replaced by $/ B /$ from ${ }^{*}$. In Kigmbu and KiMbeere we have shift from a bilabial position to a labio-dontal position i.e. $\cdot P>/ N /$. Both of these nrocesses hav happened throuph weakening.

After p-lenition * B loss was rencated in all these four dialects. These now Iricatives have began to drop
out. The only exambles that we can give are ava ard e3a 'here'. The first one occurs in Kizebu ani kiMbeere while the second one occurs in Kiuichurll and Killdia. Bcth of these words cove from pona. For further discubuinns on this see 2.2 .0 to 2.2 .3 .

Another examnle of an intrinsic diachronic rule ordering io Dahl's law that we discussed in 4.1.4. In that section we ordered the introduction of Dahz"s law before is reduced to / / Ve claimad that the only reason why Dahl's law was violated by this change was because it vas already in the dialects. Had it coec after the change fron ats to / / / the rule would have been general in all the dialects. There would have been no need for any dialect e.g. vestern dialects to violate thie rule.

These examples of ordered historical mues vere intended to show that certain sound changes caanot be explained unless we first establioh the historioal sequenoe. These examoles, also, exemplify the difference betweon diachronic and synchronic phosology. This is a necessary diatinction in our theory of sound change.
5.6 Rule interpretation: nad Sound change.

Up to this point this chanter has been discusaing the relationship between underlyinf ard surface forms. We shall now turn to the riles and tip inclications any rule or get of rules has for the whole theors of sound

#### Abstract

change. Many sections of this study will have aade certain claims and implications that ve shall discuss in this section. Before ve addrese ourselves to rule iaterpretation we mat understand what a linguistic theory is supposed to do.

A linguistic theory is supposed to emable us to
write explanatorily adequate gramars. 1 gramar attaina explanatory, adequacy if it accounts for the intuitions of an idealized apeaker of the language for whicb it is writton (cf. Chomaky 1965). Chomsky goes on to claí that such an explanatorily adequate gramar should be the best among all possible gramars written for the given data. All these claine are made within T. $\mathrm{l}_{\mathrm{i}} \mathrm{G}$. as exemplified by Chomaky and Halle (1968).

This section will evaluate these claims by interpreting rules written to account for given phenomena. The firat exaraple is that of Dahl's law discussed in 4.1.5.1. is we noted in that section this rule has been violated by the surfacing of $[8]$ and $[0]$ in adjacent syllables. We traced $/ d /$ backwards and found that it came irom "ts. No also found out that no dialect in this region has shown any siens, of $10 /$ whether as an allophone or an a phoneme. It was ther fore concluded that there was no justification for positing $/ 0 /$ as underlying form of /d/ (cf. rules 89 and 30 in 4.1.5.1.). Rule 30 is repeated here for ease of referenc:-
6. $C$

The reasons for positing $/ \theta$ / as the underlying phoneme of [d] were based on the principle of minimum distance between surface and underlying forms. According to T.G.G. only one feature changes ie. -voice to trice. This mil is, in T.G.G., a highly valued rule because it has the -inimus number of features and also because it enables us to wite one exceptionless Dahl's law.

Rule 30 in 4.1 .5 .1 is possible because T.G.S. allows abstract representation. Tais abstraction can be best explained by the following quotation from Chen and Wang (1975). They say,

While the abstract approach tends to lead to
surreptitious internal reconstruction, the concrete approach makes more accurate predictions about the future course of linguistic change.

There cannot be better sumary of T.G.G. than the above quotation.

Turning to our examples we can now see why T.G.G. would go wrong by positing / $/$ / se the underlying form of / / $/$. This was wrong because the sound does not exist in these dialects. The absence of this sound meant that no dialect
would reestablish uniforaity by losing the voicing rule.
Eastern dialects reestablished uniforeity by replacing [8] with [k] before [d]. Here T.G.G. has failed the test of rule interpretation and sound change.

The second reverition of the T.G.G.'s failure is
language acquisition Children frim th" vestern dialerte always begin by placing [k] before [d]. They only adjust this after long periods of corrections by old speakers. If we take this example of language acquisition we shall find that children do not acquire abstract forms. They acquire concrete sounds.

Another example that proves that abstract approach
wrong is that of Yavelmani. This Yavelmani example is discussed by Venneaann (1973) and Kisseberth (1969). This case involves the echo vowel harmony. Before we look at the examples let us see what the old Yawelmani vowel harmony was. Vennemann calle this rule Pre-Yavelmani Harmony (PYH). The rule is as in 7.
7. $V \rightarrow\left[\begin{array}{l}* \text { high } \\ B \text { back } \\ \gamma \text { round } \\ -1 \text { ong }\end{array}\right]$
$\int-\left[\begin{array}{l}V \\ \text { Whigh } \\ \text { Brack } \\ \gamma \text { round }\end{array}\right]$ roots.

In course of history rule 7 has been violated by a more recent change in the language. As a result of this recent change Yawelmani has the following surface forms (only the roots are glossed).

| 8. | file:thin |
| :--- | :--- |
| tuyo:thun | urinated |
| hoyo:thin | named. |

These exemples do not agree with rule -. The firet
two examples show that $[i]$ and $[u]$ hovmanise with $[i:]$ ach [o:] respectively. On this Kuroda $(1969)^{1}$ suggests that some 0 s should come from $/ \mathrm{u} /$. The same will apply to [0]s i.e. coming I=Om/i/. In T.G.G. Iranevork the above forms vill be generated as shown $\ln 9$.
9. Underlying ?vli:thin cVyu:*hin hVyoithin

Echo:
Lowering
Surface
?ili:thin Cuyu:then hoyosthin
2110ithin Cuyoithun -
2110:thin Cujo:thun hoyoithin

Apart fron thetheoretical question of sbatraction ve have more practical question to ask. The quection le whether or not the present day Iavelani speakers bave the Pre-Iawelmani rulea. It seon uncorvincing for any Ilnguistic theory to imoly that young epeakers bave rule siaply because it was part of thoir forefathers' grammar.

In T.G. G. the echo rule must apply before lowering. The two rules are extrinsically ordered. This analysis is rejected by N.G.G. because it violates two major principles. Thesfare, the no-ordering constraint and the Strong Naturalness Condition. According to N.G.G. the oresent daj Iawelmani grammar is more complex than this. This
complication should be formally reflected within our grammar. Any grammar that retains the old simple grammar fails to account for the intuitions of native speaker.
N.G.G. claims that the former high vowels have been restructured. They are no longer high but for purposes of echo vowel harmony they function as high vowels. This is the complication that we want reflected in the grammar. For this reason we reject rule 7. Rule 7 is replaced by rule 10 which shows special markers on low vowels that function as high ones. Thlemarkers will tiger the vowel harmony rule. The rule is as follows:-

Rule 10 has two rules within it. The first rule applies when echo vowel harmony rule is trigered by low vowels that are marked HI . This is a triger that these nonhigh rowels will operate like high vowels in rowel harmony. The other section deals with the actual hi sh vowels that operate like the PYH.

Rule lo does not only show formal complexities but also revels the complications in real language. These,

#### Abstract

conplerities can be lost by a reanalysis of the echo harmony rule. In N.G.G. the special aerkers vill be loot 80 that low vowels harmonise vith low vowels and bigh Fowels with high vowels. T.G.G. claine that the epeacers will lose the lowering mie thus going back to the PreYavelmani situation.

In order to test which of these two predictioss is right we shall appeal to comparative studies. A comparison between Iawelaani and Chukchansi (a closely related dialect) reveals the followingi-

| 11. Iawelmani | Chukchansi | Olose |
| :--- | :--- | :--- |
| ?11e:hin | Teleihin | fanned |
| Sudok'hun sodok'hun | removed. |  |

Chukchansi examples show that what was lost was not the lowering rule but the special warkers on $/ e: /$ and $/ 0: /$. AB with the Dahl's law examoles ahstraction has been proved wrong. These are enough examoles to show that a theory that posits abstract folms does not account lor the intuitions of native speakers. Note that these abstract Porms are posited so as to achieve lormal simplicity that can neither be tested nor proved right by either comparative studies or language acquisition.

Examples given in this section show that both abstract representation and absolute neutralization should be rejected in our theory of sound change. By rejecting
these concopts ve also question the linguistic theory that adrocates them. The theory lacks enough constrainte to disallow it from such wrong predictions of sound change.

Our theory of sound change should be liaited in way that it will only make claims and predictions thet are accurate. These claims and predictions should be testable in of ther comparative studies or language acquisition. This is the only way to find out if our theory of sound change is correct. To rely on foral elegance and on untestable generalizations is to divoree our grammars from the ative sueakers.

## Footnotes:

1. Kuroda, S-Y. (1969) Iavelmaní, Phonology; Kuroda at

Page 11 finds that there are two types of $/ 0:$ s. There are those that harmonize with $[0]$ and those that harmonise with $[\mathrm{a}]$, to this be says This makes use suspect that $[0]$ in $\left[\% 0^{-t}\right]$ may be generatively different frov[0]in [go b] and may actually be derived irom/u/, which, as has been noted, is missing on the phonetic level."

It is not surprising that Kurode should suggest that $[0$ ] should be generated from /u/ which never surfaces. Be was writing in T.G.G. framework which allows context free neutralization but which N.G.G. has disallowed.

## APPENDIX 2

List of informante:
For this study a total of sixty five informants were intervioved. The following list is therefore a (short) list of the main informants. These are people who did not claim competence in more than one dialect of S. Mt. Keaya. They aleo did not apend most of thoir lives outside thoir dialect areas. Those who epent moet of their lives outalde their dialect areas have not beon used as main informanto:-
(a) Eabu:

1. C.N.R., age 25; born in Gaturi location. Re has never lived outside Eabu for more than three months. He speaks Ki-Rabu and English.
2. A.W.K., age 23; born in Mbeti and grev up in Ngandori. She never left her home area for more than three months until she was 20. She speake Ki-bebu and inglisk.
3. E.W., age 21; born in Kjeni. She has never lived outside Enbu. She speake Ki-Einbu and Einglish.
4. J.N., age 18; born in Ngandori. He has lived all his life in Embu. He speaks Ki-Enbu and some English.
(b) Mbeere:
5. L.M.M., age $24 ;$ born in Gachoka. She never left Mbeere until she wan 21. She speaks Ki-Mbeere and Einglish.
6. S.K., age 18; born in Mbeti. He speaks Ki-Mbeere only.
7. I.N., age 19; born in Gachoko. She speak Ki-Mbeere and English.
(c) Gichugu:
8. J.M., age 10; born in Kabari. He spoaka Ki-gichugu only.
9. N.M., age 80 ; born in Kabari. He speake Ki-Gichugu only.
10. M.W.N., age 22; born in Ngariama. She has lived all hor life in Kirinjaga. She speake Ki-Gichugu and English.
11. I.M., age 35; born in Ngariama. She spent two jears in Fabu. She speake Ki-Gichugu, English and Kiowahili.
(d) Ndia:
12. S.K., age 75; borm in Mwirua Locetion. Ho speake KI-Mdia only.
13. S.N., age 55; born in Mwirua Location. She
grow up in the sane place. She later moved Tebere. She speake Ki-lidia only.
14. J.N.K., age 23; born in Mutira Location. She lived in her area untll she was 20. She speaks Ki-Ndia and English.
15. J.K., age 25 ; bom in Kiine. He rpeake KioNdia English and Kiswahili.
(0) Mathira:
16. K.M., age 60 ; born near Karatina. Left his area during second world war. He speaks Ki-Mathira and Kiswahili.
17. M.M., age 20; born in Kirimukuju. She has lived all her life in Mathira. She speaks Ki-Mathira and Eaglish.
18. J.W., age 18; born near Karatina. She sneaks Ki-Mathira.
19. E.G., age 23; born in Ngandu Location. She has spent wost of her life in Mathira. She speaks Ki-Mathira and English.
(f) N. dialect:
20. B.W., age $11 ;$ born in Thigingi. He sueake Kikuyu only.
21. L.W.K., age 24; born in Mahiga. She bas lived in Mahiga for all this time. She speaks Kikusu and English.
22. R.W., age 20 ; born in Kiru. She bas spent all her life in Kiru. She speaks Kikugn and English.
23. L.W.M., age 22; born in Tetu. She has apent all her life in Tetu. She spoake Kikuyu and English.
24. W.I., age 80; born in dikondi. She apeake Kikuyu only.
(g) S. dialect:
25. J.N., age 28 ; born in Mugoiri. He has spent all this tiae in Mugoiri. He speake Kikuyn and English.
26. M.K., age 13 ; born in Muruka. He speaks Kikuyu onIy.
27. W.K., age 26 ; born in Githunguri. She bas apent all her time in Githunguri. She speaks Kikugu and English.
28. H.N., age 23; born in Kinoo. She has lived all her life in Kinoo. She speaks Kikuyn, Kiswahili and English.
29. M.N., age 35 ; born in Ndeiya. He has spent all his life in Kiambu. He speaks Kikuyu, Kiswahili and English.

[^0]:    The above discussion is a roflection of emonraameats caused by dialectal differences which may bave reulted frow semantic shifts. Even where words are not embarmsing, poopla are quick to point out that one is of this of that dialect because of his vocabulary. One such a case is the use of the word pfers in s. dialect. To thea anybody who sayo nfarà must be from Nyeri.

[^1]:    The altornative to the above suggestion is that
    -Jtc was niatekenly soparated into J-tc. The eoparation
