THE EFFECT OF TEMPERATURE ON
THE STABILITY OF PENICILLIN - V
POTASSIUM PAEDIATRIC SYRUP

BY

JOHN MACHAYO

SUPERVISOR J.O. OGETO
LECTURER IN PHARMACEUTICAL CHEMISTRY
DEPARTMENT OF PHARMACY
FACULTY OF MEDICINE
UNIVERSITY OF NAIROBI
NAIROBI, KENYA.
ACKNOWLEDGEMENTS

I wish to convey my special thanks to:-

- My project Supervisor, Mr. Ogeto whose
tireless and patient guidance put me
through this project.

- Lecturers, other members of staff and
students at the Pharmacy department for
providing the peaceful environment necessary
for the success of such tedious work.

- Mr. Mureithi and Mr. Thuranira,
Laboratory technicians in the Pharmaceutical
Chemistry Section for being most helpful

- My uncle Mr. J. Namidi for his constant support.

AIM:

To investigate the stability of the reconstituted penicillin – V – Potassium syrup and the effect of temperature on the rate of degradation with the view of advising Kenyans on the stability and suitability of using this syrup for up to seven days after reconstitution.
The effect of temperature on the stability of penicillin-V potassium paediatric syrup.

INTRODUCTION:

Paediatric medication is a delicate issue due to the lack of development of some metabolic enzymes in infants such as glucuronyl transferase, and hence the possibility of toxic effects with relatively small doses of various drugs e.g. chloramphenicol (1).

For this and other reasons like the inherent toxicity of various drugs has led to the wide use of penicillin-V syrup in various government hospitals throughout the Country. This can be attributed to the relatively wide safety margin of penicillin compared to other drugs with the same spectrum of activity also penicillin is relatively cheap. The spectrum of penicillin also has a telling effect on the frequency of its use as it is effective against many common infections caused by gram-positive cocci and bacilli: streptococci, pneumococci and gonococci are invariably sensitive save for an alarming degree of resistance developing in gonorrhea (2).

Penicillin produces its bactericidal activity by interfering with the cell wall development in sensitive microorganisms. Specifically by inhibition of biosynthesis of the dipeptidoglycan strand that is needed to produce strength and rigidity to the cell-wall.
Penicillins acylate the enzyme tripeptidase thus rendering it inactive for its role in forming a cross-link of the two peptidoglycan strands by transpeptidation and elimination of D-alanine (3).

It is therefore not surprising that pen-V syrup is found in many government hospitals such as in Nairobi at Kenyatta National Hospital, in Mombasa at the Coast General Hospital and other hospitals, clinics, and dispensaries in various other locations all over Kenya namely, Lodwar Mandera, Moyale, Garissa, Kitale, Eldoret Nakuru, Kisumu, Nanyuki etc.

Kenya is a country whose climate differs from place to place and for this reason, temperatures vary with different regions.

Data from the metrological Department shows that the average temperatures at various stations vary with months. Generally lower in the rainy seasons and high during the dry periods.

The Data below illustrates this more clearly.

<table>
<thead>
<tr>
<th>Station</th>
<th>Month</th>

<tr>
<td>Enебess (Kitale)</td>
<td>August</td>
<td>17°C</td>
</tr>
</tbody>
</table>

From these statistics it can be seen that the temperatures range between 10°C to 35°C.

The majority of the Kenyan population live in the rural areas where facilities for refrigeration do not exist, hence any drug dispensed to them will be stored at the existing temperatures at which ever place they stay.

On the commercially available penicillin-V potassium syrup labels, distributed to the various health centres through the central medical stores, the instructions state that the syrup should be used for a maximum of seven days after reconstitution regardless of the temperatures of the areas where it is being used.

An example is the pac laboratories the label states that store in cool place Discard contents 7 days after reconstitution.

It is however believed that the rate of degradation of penicillin V syrup is temperature dependent. This degradation occurs by hydrolysis and is catalysed by the presences of base or acid. An enzyme found in some microorganisms which imparts resistance to penicillin, \( P-lactamase \) also catalyses penicillin hydrolysis:
The reaction can be represented as follows:

**In base or β-lactamase.**

\[
\begin{align*}
R-\text{CONH} & \quad \rightarrow \quad R-\text{CHO} \\
\downarrow & \quad \text{OH}^- \text{ or β-lactamase} \\
\text{R-CONH} & \quad \xrightarrow{\text{H}_2\text{O}} \quad \text{Penicilloic Acid} \\
\downarrow & \quad \text{Penicilloic Acid} \\
\text{R-CONH} & \quad \xrightarrow{\text{H}^+ \text{ or } \text{H}_2\text{O}} \\
\end{align*}
\]

**In Acid**

\[
\begin{align*}
\text{RCONH} & \quad \rightarrow \quad \text{Penicillieic Acid} \\
\downarrow & \quad \text{Penicillieic Acid} \\
\text{RCONH} & \quad \xrightarrow{\text{H}^+ \text{ or } \text{H}_2\text{O}} \\
\end{align*}
\]

\[
\begin{align*}
\text{RCONH} & \quad \rightarrow \quad \text{Penicillioic Acid} \\
\downarrow & \quad \text{Penicillioic Acid} \\
\text{RCONH} & \quad \xrightarrow{\text{H}^+ \text{ or } \text{H}_2\text{O}} \\
\end{align*}
\]

\[
\begin{align*}
\text{RCONH} & \quad \rightarrow \quad \text{Penicillioic Acid} \\
\downarrow & \quad \text{Penicillioic Acid} \\
\text{RCONH} & \quad \xrightarrow{\text{H}^+ \text{ or } \text{H}_2\text{O}} \\
\end{align*}
\]
An examination of the penicillin structure shows it contain a fused ring system of unusual design, the β-lactam thiazolidine structure. The β-lactam is highly unstable hence the ease of hydrolysis.

The products of hydrolysis are not active antimicrobial agents, therefore with hydrolysis the activity of the suspensions decreases and with this the therapeutic efficacy.

This solution was prepared by the B.P. (1980) method by weighing accurately by difference 10.5421g of sodium hydroxide pellets and dissolving them in sufficient carbon dioxide free water to produce a volume of 250 ml in a volumetric flask.

The carbon dioxide free water was prepared by boiling the water and allowing it to cool in a closed container.

The exact strength of the solution was not determined as this was necessary for the experiment.
Hydrochloric Acid VS Hcl=36.46

This solution was prepared by diluting a stock solution of 32% Hcl.

From this solution each millilitre contains 0.32 g of Hcl.

A solution of 1 molar Hcl contains 36.46 g of Hcl in 1000 mls of water and \((\frac{36.46 \times 250}{1000})\) g in 250 mls

\[= 9.115 \text{ g in 250 mls.}\]

The volume of the stock solution required to produce 9.115 g is given by

\[(9.115 \times 100) = \frac{28.48 \text{ mls.}}{32}\]

28.5 mls of this stock solution was therefore measured in aburette and diluted to 250 mls with water in a volumetric flask to produce a one molar Hcl solution.

0.02 M Sodium Thiosulphate VS Na\(_2\)S\(_2\)O\(_3\) \(5\text{H}_2\text{O}= 248.2\)

This solution was prepared by diluting a 0.1% solution.

<table>

Sodium Carbonate

| Wt. of sample + weighing bottle | 16.7457 g |
| Wt. of empty weighing bottle   | 16.6333 g |
| Wt. of sodium carbonate       | 0.0524 g  |

6.2772 g of sodium thiosulphate and 0.0524 g of sodium carbonate were dissolved in sufficient carbon dioxide free water to 250 mls in a volumetric flask. 200 mls of the resulting solution was then diluted to one litre in a volumetric flask using carbon dioxide free water to produce a 0.02 m solution.

The exact strength was ascertained using this 0.02 m solution by dissolving an accurately weighed potassium bromate as follows.

Potassium Bromate

| Wt. of sample + weighing bottle | 16.1808 g |
| Wt. of empty weighing bottle   | 15.9722 g |
| Wt. of sample (KBrO₃)          | 0.2086 g  |

The 0.2086 g of KBrO₃ was dissolved in sufficient water to produce 250 ml. to 50 ml of this solution 2g of KI and 3 ml of 2m hydrochloric acid were added.
10 ml aliquots of this solution were then titrated with the 0.02 M sodium thiosulphate using starch mulitgate as indicator.

<table>
<thead>
<tr>

<tr>
<td>1st Burette Reading</td>
<td>0.0</td>
<td>20.0</td>
</tr>
<tr>
<td>Volume of Na₂S₂O₃</td>
<td>13.4</td>
<td>13.4</td>
</tr>
</tbody>
</table>

From the B.P (1980) we know that 1 ml of 0.1 M sodium thiosulphate is equivalent to 0.02784 g KBrO₃.

Therefore 1 ml of 0.02 M Na₂S₂O₃ = 5.5568 x 10⁻⁴ KBrO₃

The amount of KBrO₃ weighed was 0.2036 g. This was dissolved in 250 mls and 50 mls of the resulting solution KI and 2M Hcl was added. 10 ml of this was what was titrated with the thiosulphate.

Therefore amount of KBrO₃ present in the 10 mls = \( \frac{0.2036}{25} = 8.344 \times 10^{-3} \) g.

This was equivalent to 13.4 ml of the thiosulphate solution.

Therefore 1 ml of the 0.02 M thiosulphate is equivalent to

\( \frac{8.344 \times 10^{-3}}{13.4} = 6.226 \times 10^{-4} \) g of KBrO₃

The standardization factor is therefore given by

\[
P = \frac{6.226 \times 10^{-4}}{5.5568 \times 10^{-4}} = 1.118
\]
0.01 M Iodine VS I = 253.8

<table>
<thead>
<tr>
<th></th>
<th>Iodine</th>
<th></th>
<th>Potassium Iodine</th>
<th></th>
</tr>

<td></td>
</tr>
<tr>
<td>Wt. of Iodine</td>
<td>3.2755 g</td>
<td>Wt. of Iodine</td>
<td>5.0135 g</td>
<td></td>
</tr>
</tbody>
</table>

The 0.01 M was made by diluting a 0.05 M solution.

The KI was dissolved in a minimum amount of water to this 3.2755 g of Iodine were added and allowed to dissolve the solution was then made to the 250 ml mark using distilled water.

The resulting solution is 0.05 molar from the relation ship

\[ C_1 V_1 = C_2 V_2 \]

were \( C = \) Concentration and \( V = \) volume

\[ V_2 = \frac{C_1 V_1}{C_2} \]

\[ V_2 = \frac{0.05 \times 100}{0.01} = 500 \text{ mls.} \]
That is 100 ml of the 0.05 M solution was diluted to 500 ml using distilled water to produce the 0.01 M solution.

The exact strength of the resulting solution was determined by titrating 10 ml against the standardized 0.02 M sodium thiosulphate solution using starch Lucilage added towards the end as the indicator.

<td>9.6</td>
<td>9.5</td>
<td>9.5</td>
</tr>
</tbody>
</table>

Average volume = 9.5

The standardization factor of the thiosulphate solution was 1.118

Using the relationship

\[ N_1 V_1 F_1 = N_2 V_2 F_2. \]

where: 

- \( F \) = factor
- \( N \) = Normality
- \( V \) = Volume

The \( F_2 = \frac{V_1 F_1}{V_2} = 9.5 \times 1.118 \)

\[ \frac{V_2}{10} \]

\[ = 1.0621 \]
Buffer Solution

The Buffer that was used was the acetate buffer as in the B.P.C (1973). This was freshly prepared each day of analysis. Made up of $5.44\% \text{ W/V}$ sodium acetate and $2.40\% \text{ W/V}$ glacial acetic acid. The sodium acetate was first dissolved in a small amount of water, the glacial acetic acid added and the resulting solution made up to volume with water.

Starch Indicator Solution.

This was prepared by the B.P (1930) method by titrating $0.5g$ of soluble starch with $5$ mls of water. To this sufficient water was added to produce about $100$ ml with continuous stirring. The solution was then boiled for a few minutes, cooled and filtered.

A fresh solution was prepared on each day it was required.
The method used in the analysis was based on the fact that the average mean temperatures in Kenya were found to be in the range of 10°C to 35°C with this in mind an upper temperature limit of 40°C was chosen and a lower limit of 5°C. Two other intermediate temperatures were used; these were room temperature which averaged at about 20°C and the second temperature of 35°C.

The syrup after reconstruction was divided into three samples, in the first experiment the 5°C sample was stored at the bottom of a refrigerator the room temperature sample was stored on a bench while the 40°C regulated thermostatically at 40°C throughout the whole period of analysis.

In the second experiment the 5°C and room temperature sample were stored as before and the 35°C was stored in the same water bath this time regulated at 35°C.

Small amount were removed from each sample for analysis without disturbing the incubation temperatures as much as possible.

The assay was carried out using the Iodometric method for penicillin. This method originally described by Alicino has been generally accepted as a dependable analytical method for the determination of penicillin potency.
The assay is probably one of the most rapid, accurate and specific chemical test available for penicillins. It compares favourably with the microbiological cup-plate method in accuracy and it has the advantages of speed, precision and economy.

It is based on the fact that the alkaline hydrolysed penicillin molecule reduces between six and nine moles of Iodine per mole of penicillin molecule depending upon the penicillin being assayed. The intact molecule does not reduced Iodine and so the difference between the number of moles reduced by a control sample and a fully hydrolysed sample would give the amount of intact biologically active phenoxyethyl penicillin potassium.

Finholt et al (6) used the assay in the Kinetic analysis of penicillin (benzyl penicillin) the assay was also used by Hon and Poole in the Kinetic analysis of ampicillin (7) as well as the determination of the amino acid nature of ampicillin. In their work on chemical reactions involved in penicillin allergy, Kinetics and mechanism of penicillin aminolysed. Akira Tsuji et al (8) used the same Iodine method. The procedure has been also used by Savello et al (9) in their work on the stability of sodium ampicillin solutions in the frozen and liquid states.
The procedure used for the assay in this study is that found in the B.P.C (1973). The gramles for reconstitution for this study were supplied by PAC laboratories
PAC PEN
Dry gramles for reconstitution as syrup
Mfg. Pac laboratories Ltd.
Batch no 20633
Date of Manufacture 6/82
Expiry date October 85
Label claim each 5 ml of syrup when freshly prepared contains penicillin V potassium equivalent to 125 mg penicillin V. B.P
The gramles were reconsituted as recommended by the manufactures by adding 1950 ml of distilled water in stacion with shaking until all was dissolved.
The white powder when reconstituted gave a pinkish viscous syrup with the characteristic odour of penicillins.

The reconstituted syrup was then divided into three conical flasks which were tightly stoppered and stored at 5°, room temperature and 40°C as explained earlier the second sample was treated like wise and stored at 5°C, room temperature and 35°C as explained earlier.
These samples were then analysed at intervals as shown in the results for the total penicillins over a period of seven days which is the period recommended by the manufacturers as the number of days for which the reconstituted syrup may be used.

This long term storage was chosen instead of an accelerated stability test as this provides a better approximation to normal conditions as it has been reported that some reactions occur at elevated temperature which would otherwise not occur at normal storage temperatures (10). Also a period of seven days was reasonably short and convenient.

Immediately after reconstitution the syrup was analysed to determine the penicillins present; this was done by accurately weighing a quality of the syrup equivalent to about 0.05 g phenoxy methyl penicillin and diluting it to 50 ml with distilled water in a volumetric flask. 10 ml were transferred to a wet stoppered 'Iodine flask' and 5 ml of \(\text{NaOH}\) sodium hydroxide added and allowed to stand for 20 minutes. This is the alkaline hydrolysis which cleaves the \(\beta\)-lactam ring to produce the corresponding penicilloic acid.

\[
\text{RCONH} \quad \overset{\text{OH}^-}{\longrightarrow} \quad \text{RCONH} \quad \text{COOH}
\]

\[
\text{R} = \text{OCH}_2
\]
The time of 20 minutes was important to ensure that the same period was given for the hydrolysis for comparative purposes and is thought to be sufficient for complete hydrolysis to occur.

20 ml of a freshly prepared buffer solution containing 5.44% w/v sodium acetate and 2.40% w/v glacial acetic acid were added this in effect stopped further hydrolysis by the base. 5 ml of N/1 hydrochloric acid were then added and this converts the penicilliace to D-penicilliamine.

\[
\text{RCONH} - \text{C} \rightarrow (\text{CH}_2)_2 - \text{C} \rightarrow \text{C} - \text{COOH}
\]

25 ml of 0.02 N Iodine solution where then added and the flask stoppered using a wet stopper and allowed to stand for 20 minutes protected from light to avoid light catalysed free radical reaction of Iodine.

The Iodine oxidises the D-penicilliamine almost quantitatively to the corresponding disulphide.

\[
2(\text{CH}_3)_2 - \text{CH} - \text{COOH} \rightarrow (\text{CH}_2)_2 - \text{C} \rightarrow \text{C} - \text{CH} - \text{COOH}
\]
the oxidizing power of Iodine can be denoted as follows
\[ \text{I}_2 + 2\text{e}^- \rightarrow 2\text{I}^- \]

Because Iodine is practically insoluble in water, use was made of the fact that it dissolves in solutions of potassium Iodine to form potassium Iodine which behaves in solution as free Iodine (B.P method for preparation of Iodine solution).

Care was taken in handling the Iodine solution as Iodine being volatile was stored in tightly stoppered glass bottles and the standard solution was not collected from the bulk in beakers or open vessels. When measured from suitable containers into burrettes, it was titrated without delay as these precautions have to be observed if satisfactory results are to be obtained.

The excess Iodine was then titrated with 0.02 N sodium thiosulphate using starch mucilage as an indicator added towards the end of the titration.

\[ 2\text{S}_2\text{O}_3^{2-} \rightarrow \text{S}_4\text{O}_6^{2-} + 2\text{e}^- \]

\[ \text{I}_2 + 2\text{e}^- \rightarrow 2\text{I}^- \]

therefore \[ 2\text{S}_2\text{O}_3^{2-} \equiv \text{I}_2 \equiv 2\text{e}^- \]

A blank (control) determination was carried out simultaneously by taking a further 10 ml of the diluted solution and adding 10 ml of the acetate buffer solution.
to oxidized any of the penicillins that had already hydrolysed in solution. The flask was stoppered with a wet stopper and allowed to stand for 20 minutes protected from light.

The excess Iodine was the back titrated with the 0.02 N sodium thiosulphate solution using starch micilage added towards the end of the titration.

These determination were done in duplicate.

The total penicillins calculated as phenoxyethyl penicillin potassium were determined by repeating the procedure with a standard (BCRS) phenoxyethyl penicillin potassium obtained from the drug research and analysis unit.
RESULTS

Standard BPCRS sample from DARU for this sample each mg of pen V. potassium BPCRS is equivalent to 0.9019 mg total penicillins calculated as C₁₆H₁₈N₂O₅.₅

₀₀₀ wt of standard equivalent to 0.06 g pen V. potassium = 0.06 x 1 = 0.0665 g
₀.₉₀₁₉

Sample taken for analysis

| wt. of empty 50 ml vol. flask + standard | 38.2023 g |
| wt. of empty flask | 38.1356 g |
| wt. of sample | 0.0667 g |

Sample II

Percentage of Total Penicillins Vs Time (Days)
Discussion:

Before any medicine is bought by the central medical stores, it must comply with the official standards of purity and content as certified by (DARU) the drug analysis and research unit.

However after reconstitution the content of active ingredient is not routinely analysed hence the pharmacist will be left with little choice but to follow the manufactures instructions on use.

From the foregoing experiment it will be seen that those instructions are not always correct for all existing climates.

The BPC (1973) states that the syrup should contain at least 80% of the original penicillin V for it to be therapeutically useful.

From the results obtained in this experiment it can be seen that if the syrup is stored at 5°C, the manufactures instructions are quite accurate and it still retains the required about of pen V over the seven day period.

However at room temperature, (the average room temperature in Nairobi over the period of experiment was 20°C). The seventh day does not meet the requirements exactly as the first sample contained 79.7% of the original penicillins while the second retained 78.2%.
As the temperatures increase, the rate of degradation also increases as shown by the samples stored at 35°C and 40°C. These cross the 80% limit after about 3½ and 2½ days respectively which denotes that if used on the fourth and third days respectively they do not contain the penicillins required that is the dose prescribed by the doctor is not dispensed by the pharmacist as what the pharmacist would dispense at this period would be an underdose as per the doctors instructions.

In conclusion it is therefore evident that in those regions where the average temperatures are greater than or equal to 20°C the manufactures instructions are not compatible with official B.PC (1973) standards.

Pharmacists at places like Mandera, Mombasa, Lowdar and Garissa should be made aware of this fact with the view of advising the patients on how best to use the medicine.

Some suggestions of overcoming this problem are:—

Usually the pharmacy, hospital or clinic is located in a region where a refrigerator is available if not these should be installed using generators or the more portable paraffin using refrigerators.
This would enable the reconstituted syrup to be stored at the low temperatures with the concomitant slower degradation rate with this possible, the patients in such areas should only be given a three day dose of the syrup and if this is not enough for cure the patients should be instructed to come back for a second dose after three days.

Alternatively the dry granules which have a much longer self-life should be dispensed in such areas and the patients should be shown how to reconstitute the granules of course they should be dispensed in three day batches so that the patient is given two packages of granules for six days therapy one containing only an average three day dose. These smaller batches could be obtained from the manufacturer on order (more expensive as more packaging material is required) or the pharmacy could be used to do the repackaging for such areas.

Chemically derivatives with a slower rate of degradation than pen V or different types of drugs which do not suffer from hydrolysis to the same extent as penicillins but have the same spectrum of activity and efficacy could be employed in such areas. An example being the Depot injections of procaine penicillin and Benzathine penicillin.
An investigation on the effect of the Acetate and phosphate buffers on Benzyl-penicillin analysis.

Introduction:

The recommendation of the buffer to be used in the analysis of benzyl-penicillin using the Iodometric method differs from the manufacturer - Beecham, and the British Pharmacopoeia Commission the publishers of the British Pharmacopoeia.

The manufacturers recommend the phosphate buffer and claim that the use of the acetate would yield different results. The pharmacopoeia commission on the other hand use the acetate buffer and claim that the phosphate buffer gives similar results.

A literature survey shows that some buffers have an effect on the results obtained.

In the J. Pharm. Sci Vol 65 August 1976 some workers have shown using the citrate buffer that the rate of degradation of penicillin was directly proportional to the buffer concentration increasing with increase in concentration. This they explain to be a result of the citric acid at pH 2.7 being present as the dihydrogen citrate anion which is known to have a catalytic effect on the degradation of penicillins.

It has also been shown that the effect of the buffer may also be influenced by the pH at which it is used. This is evident by the pH-rate profile determined by Brodersen at 30°C and more recently by Finholt, Jurgensen

From their work the pH of maximum stability was found to be pH 6.75 with a narrow range near the maximum.

The calculated half-life at pH 6.75 and 30°C was $3.3 \times 10^6$ sec. or 3 days with a computed shelf-life of six days.

Further work has shown that the dihydrogen citrate ion, the mono-hydrogen phosphate ion and the Borate ion have a catalytic effect on the benzylpenicillate ion whereas acetic acid catalyses the degradation of benzylpenicillinic acid. Metal ions have also been shown to catalyse the hydrolysis whose overall kinetics is observed to be first order (chemical stability of pharmaceuticals by Kenneth A. (Connors).

With this in mind, the following experiment work was carried out to access the practical effect on benzylpenicillin analysis using two buffers. That is the phosphate buffer and the acetate buffer.
Reagents:

The Acetate Buffer

Was prepared as in the B.P. (1980) using 5.44 percent w/v of Sodium acetate and 2.40 percent w/v of glacial acetic acid. Both reagents were of analar grade and the buffer was freshly prepared. The pH was determined using a pH meter pH 5.4.

Phosphate Buffers:

Were prepared according to the USP XIX by using appropriate quantities of dibasic potassium phosphate and mono basic Potassium phosphate both of analar grade and adjusting the pH using 18N phosphoric acid or 10N Potassium hydroxide pH ± 0.05.

The buffers prepared were of pH 5.4, 6.2 and 7.6.

The other reagents used were prepared in the same manner as in the previous experiment namely:

- 0.02N Iodine Vs F = 1.000
- 0.02N Sodium thiosulphate Vs F=0.9634
- 1N Sodium Hydroxide
- 1N Hydrochloric acid
- Starch mucilage
EXPERIMENTAL

The analysis was carried out on crystalline benzylpenicillin Sodium B.P. Batch Number F570 EL cordially supplied by MAC'S Pharmaceuticals. The standard was also supplied by the same company.

The method used in the analysis was that found in the B.P.(1980) for assay of benzylpenicillin Sodium injection.

Two determinations were carried out for each buffer and each pH value for the phosphate buffers.

0.1g was accurately weighed into a 100ml flask and sufficient distilled water added to volume.

10ml were then transferred to a stoppered flask and 5ml of molar sodium hydroxide added and allowed to stand for twenty minutes.

20ml of the freshly prepared appropriate buffer was then added, 5ml of molar hydrochloric acid and 25ml of 0.01M Iodine VS. The flask was then closed with a wet stopper and allowed to stand for twenty minutes protected from light.

The excess Iodine was then titrated with 0.02M Sodium thiosulphate VS using starch mucilage as indicator added towards the end of the titration.

To a further 10ml of the initial solution 20ml of the appropriate buffer was added and 25ml of 0.01M Iodine VS and allowed to stand for twenty minutes, protected from light. The excess Iodine was then titrated with 0.02M Sodium thiosulphate VS using starch mucilage as indicator added towards the end of the titration.
The difference between the two titrations represents the volume of 0.01M Iodine VS equivalent to the total penicillins present.

The total penicillins content was calculated as $\text{C}_{16}\text{H}_{17}\text{N}_{2}\text{NaO}_{4}$S from the difference obtained by simultaneously carrying out the assay using benzyl penicillin sodium standard instead of the penicillin being assayed.
RESULTS

Standard Sample

Each 1.0mg of benzylpenicillin standard sample contains 1.00mg of total penicillins calculated as $C_{1617N2Na04S}$.

Wt. of 100ml flask plus std. 44.9320
Wt. of empty flask 44.8317
Wt. of std. 0.1003g.

After titration the volume of 0.02N sodium thiosulphate used were as follows

Using the phosphate Buffer pH 5.4 std 16.2
Blank 6.0
Volume used 10.2mls

This is equivalent to $10.2 \times 0.9634$mls of 0.02N Iodine

= 9.827mls

Since only 10ml of the original sample was used, the amount of Std present = $\frac{10}{100} \times 0.1003g$

= 10.03mg

Therefore 1ml of the 0.02 Iodine = $\frac{10.03}{9.827}$

= 1.021mg.
Using the Acetate Buffer pH 5.4

<p>| | |</p>

Percentage label claim = \frac{0.9394}{1.021} = 92.06\%

Summary of Results

Phosphate Buffer pH 5.4

Total penicillins in sample = 98.78\%

Acetate Buffer pH 5.4

Total penicillins in sample = 98.78\%

Phosphate Buffer pH 6.2

Total Penicillin in sample = 97.52\%

Phosphate Buffer pH 7.6

Total penicillins in sample = 92.06\%
Discussion and Conclusion

The results obtained above were done on the same day at room temperature and carried out using a method that most analysis in our analytical lab such as the Drug analysis and research unit (DARU) or a quality control lab in an industry would use. Therefore any temperature fluctuation effect would mimic normal procedures.

The results show that when the two buffers are used at pH 5.4 similar results are obtained and the buffer effect is therefore negligible.

However when the phosphate buffer is used at different pH that is 6.2 and 7.6 the results do not show good correlation with the B.P, method results.

It can therefore be seen that the pH of the buffer may significantly affect the results obtained. This may be due to the buffer existing in different ionic species at different pH.

The acetic acid sodium acetate buffer exerts its buffering effect from the fact that the acid which exists largely in molecular (non-ionized) form combines with hydroxyl ions that may be added to form the acetate ion and water. \( \text{CH}_3\text{COOH} + \text{OH}^- \rightarrow \text{CH}_3\text{COO}^- + \text{H}_2\text{O} \) while the acetate ion which is a base combines with the hydronium ions \( (\text{H}_3\text{O}^+) \) that may be added to form essentially non-ionized acetic acid and water. \( \text{CH}_3\text{COO}^- + \text{H}_3\text{O}^+ \rightarrow \text{H}_2\text{O} \rightarrow \text{CH}_3\text{COOH} + \text{H}_2\text{O} \)
The change in pH is slight so long as the amount of hydroxyl or hydronium ion added does not exceed the capacity of the buffer system to neutralize.

The phosphate buffer on the other hand is composed of two salts namely monobasic potassium phosphate \((\text{KH}_2\text{PO}_4)\) and the dibasic Potassium phosphate \((\text{K}_2\text{HPO}_4)\) when hydroxyl ions are added,

\[
\text{H}_2\text{PO}_4^- + \text{OH}^- \rightarrow \text{HPO}_4^{2-} + \text{H}_2\text{O}
\]

and when hydronium ions are added

\[
\text{HPO}_4^{2-} + \text{H}_3\text{O}^+ \rightarrow \text{H}_2\text{PO}_4^- + \text{H}_2\text{O}
\]

It is therefore apparent that the mechanisms of these two buffers are essentially the same.

At different pH however the concentration of the ions vary as in acid pH, the phosphate buffers contains the monobasic ions \((\text{H}_2\text{PO}_4^-)\) in higher concentration than the diabasic while in alkaline pH the dibasic species occur in higher concentration.

It therefore appears that the pH is more determinant than the buffer per se, as it has an effect on the buffer ionic composition. It has also been shown by other workers that the monohydrogen phosphate ion and acetic acid catalyse benzylpenicillin degradation.

Another possibility is the varying stability of the benzylpenicillin molecule itself at different pH values this may therefore lead to different results being obtained.
In conclusion therefore, the author has shown by this work that the use of the phosphate and acetate buffer may result to different results in the assay of benzylpenicillin injection if the pH of the two buffers are varied. However at pH 5.4, the results obtained show good correlation with either buffer.
