DESIGN OF A HYBRID POWER SYSTEM FOR A WIRELESS COMMUNICATION

TOWER SYSTEM

ELEPHAS KANGANGI GIKUNGI

A thesis submitted in partial fulfilment for the Degree of Master of Science in Energy

Management

DECLARATION

I declare that this work has not been previously submitted for the award of a degree by this or any other University. To the best of my knowledge, this report contains no material previously published except where due reference is made.

DEDICATION

I dedicate this thesis work to my family, Telkom Kenya workmates, church members and the MSc. Energy Management class of 2013, University of Nairobi.

ACKNOWLEDGEMENTS

My sincere thanks go to Prof. Mbuthia and Dr. Mwema for their continued support, listening, constructive ideas, patience and advice. Without them, this research work would not have come this far.

Thanks are also given to all my friends and colleagues at the University of Nairobi and Telkom Kenya With the atmosphere created, their support and sympathy, I was able to surmount the ordeals and to carry through my thesis.

Special gratitude goes to my spouse and children for their moral support throughout the research work. Their encouragement and prayers gave me a reason to keep going even in difficult times. Without their unconditional encouragement, this experience would not have been possible.

ABSTRACT

Telkom Kenya tower systems, especially those located in rough terrain, are currently powered by diesel generator sets. Diesel power generation is associated with several disadvantages which do not make it the best option. Generally, Kenya is blessed with Renewable Energy Resources (RES) which can be utilized at such towers to supply power. This study carried out measurements for wind speeds and solar insolation at Aitong, Narok site and compared these with data from secondary sources. A prototype Hybrid Powered System (HPS) was assembled and installed to record the actual RES available on site.

A HPS system was designed based on the data collected. The design process basically involved selecting the best combination of HPS system components based on their cost and power characteristics. Finally, the study compared the designed power system and the current online system at the site in terms of cost of implementation and running.

The actual on site data indicates that there is abundant RES at this site. The obtained data agrees well with data from the secondary sources consulted. The correlation is particularly close in the case of National Aeronautics and Space Administration (NASA) data. The system design optimization shows that a Net Present Cost (NPC) cost of KES 2.6 million against that of the current system of KES 21 million can be expected. The simulated Cost of Energy (COE) for the month of October is approximately Kenya Shillings (KES) 10/kWh which is better than that of Kenya Power and Lighting Company (KPLC) at KES 21/kWh over the same period.

CHAPTER 1: INTRODUCTION

1.1 Background information

Energy is vital for development of a community and nation as a whole and thus it must be produced and utilized efficiently [1]. It is argued that energy is a basic requirement for the modern life-style [2]. The ever increasing cost and environmental concerns involving conventional sources of electrical energy have increased interest in RES [3]. Technologies should therefore be developed to produce energy in an environmentally friendly manner from all energy sources. Sufficient importance should also be given to the efficient conservation of energy resources [4].

Electrical power requirements for most communication towers installed in rural areas are met by diesel generator sets. The extension of the main grid to low population areas especially those in difficult terrains is associated with high capital outlays [1]. The use of a diesel generator however, induces several environmental issues and high Operation and Maintenance (O & M) costs as summarized in Table 1.1 [5].

Item	RES	Diesel Generation		
Cost	Low O & M costs High O & M			
Pollution	No emissionsGHGs, sound, and oil spillage			
Dependency	Depends on natural and RES	Depends on oil supply		
Fuel transportation	No transportation costs	Costly to transport using tankers,		
		losses and poor quality due to		
		theft during transportation.		
Maintenance	Low maintenance	Costly, losses due to theft, and oil		
		spillage.		
Life	Longer useful life	Seven years or shorter		
Power supply	Depends on availability of RES	No guaranteed uninterrupted		
		generation		

Table 1-1: Comparison of RES with Diesel Generation[5]

Aitong, Rift Valley, Kenya (Latitude: 1.18°; Longitude: 35.25°) is hilly with an estimated terrain elevation of 1943m above sea level. Electricity consumed by the Telkom Kenya tower system in Aitong is currently supplied by two 8 kVA diesel generators, although RES are in abundance [6]. The Capital Expenditure (CAPEX) and annual Operational Expenses (OPEX) for the two diesel generators is approximately KES 5 million and KES 3.1 million respectively. Appendix 1 details the O & M for the current diesel generator. The average power demand for this tower system is approximately 1.5 kW.

In the current study, the feasibility of replacing diesel power generation in Aitong tower system with solar and wind HPS, supplemented with battery bank storage with the use of diesel generation as a back-up source, was investigated. A prototype was fabricated and installed at the site for actual data collection for comparison with secondary data from previous studies and weather stations. An HPS was then designed based on the solar and wind data collected and economic viability of the investigated system. Figure 1-1 shows the location of Aitong hill in the main Kenyan map context.

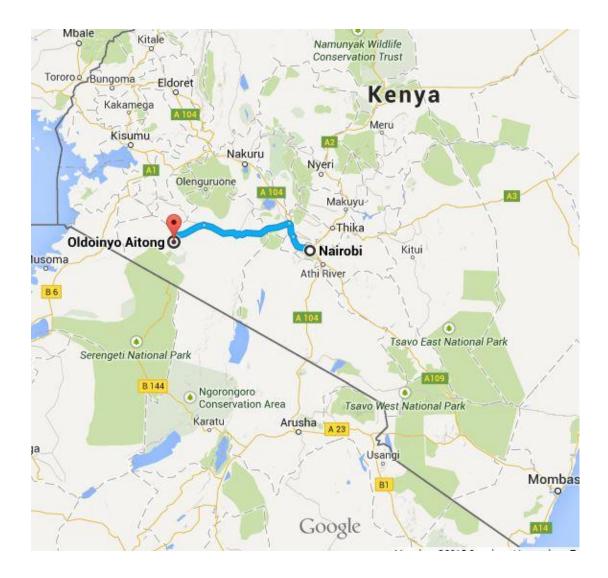

Figure 1-1: Location of Aitong from Nairobi (Google maps)

Results from the study represent additional power options to Telkom Kenya It is expected that the option suggested by these results will lead to lower O & M cost for communication towers. The cost savings realised can then be passed on to customers through reduction in calling charges leading to an increased market share and profits. An added benefit is a reduction in GHGs emission which will demonstrate the strong social responsibility characteristic of Telkom Kenya

1.2 Problem Statement

Electrical power generation using diesel engines is associated with environmental pollution while supplying power from the national grid to remotely located towers is costly. Therefore, a sustainable power supply system, which is environmentally friendly, cost effective and readily available is required.

1.3 Research Objectives

1.3.1 Main objective

The main objective of the study was to design a HPS consisting of Photovoltaic (PV), wind turbine and battery bank. The existing diesel generator set will be replaced by an optimized diesel generator which will act as a back-up power source in case the components for capturing RES are not available due to either breakdown, replacement, etc.

1.3.2 Specific objectives

- 1. To assess the solar and wind energy resource at the Aitong tower system site
- 2. To design and optimize a HPS for the communication tower system

3. To assess the economic viability of the HPS as a source of power for the tower system

CHAPTER 2: LITERATURE REVIEW

2.1 Renewable energy sources (RES)

Renewable energy comes from the sun and can be used directly as is the case with solar heating systems or indirectly as with hydroelectric power, wind power, and power from biomass fuels. RES includes solar energy, wind energy, hydroelectric power, geothermal energy, bioenergy, ocean energy, etc. There are other alternatives to sources of energy that are not renewable in nature. Although these are "alternative energy" rather than "renewable energy", they use the existing energy more efficiently than older technologies. The use of renewable and alternative energy sources can save funds, conserve energy, save the environment, and reduce over-dependence on energy supplies outside the country borders [9], [10].

2.2 Hybrid Power Systems (HPS)

Hybrid power system involves a combination of two or more modes of electricity generation devices or sources [2] such as wind turbines, PV, micro-hydro and/or fossil fuel generators. They are generally independent of centralized power grids and can be used in remote/rural areas [11], [12]. The use of RES in hybrid power generation systems reduces the reliance on expensive fuels while allowing for a cleaner generation of electrical power [13]. HPS addresses limitations in terms of fuel flexibility, efficiency, reliability, emissions and/or economics as well as

elimination of fuel transportation costs [12]. Figure 2-1 shows the schematic diagram of a basic HPS involving various sources [11].

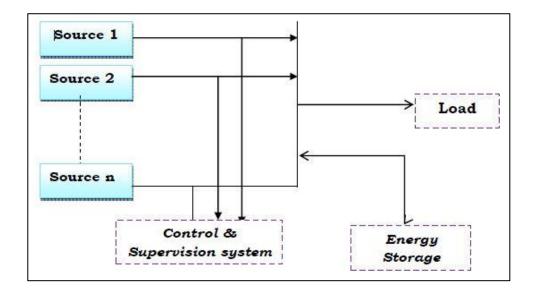

Figure 2-1: Basic HPS

In general a hybrid power system contains Alternating Current (AC) diesel generators, an AC distribution system, a Direct Current (DC) distribution system, loads, RES, energy storage, power converters, rotary converters, coupled diesel system, dump loads, load management options or a supervisory control system [14]. A schematic diagram of the possibilities available from a HPS is illustrated in Figure 2-2 showing the operation of each of these components and the interaction between them.

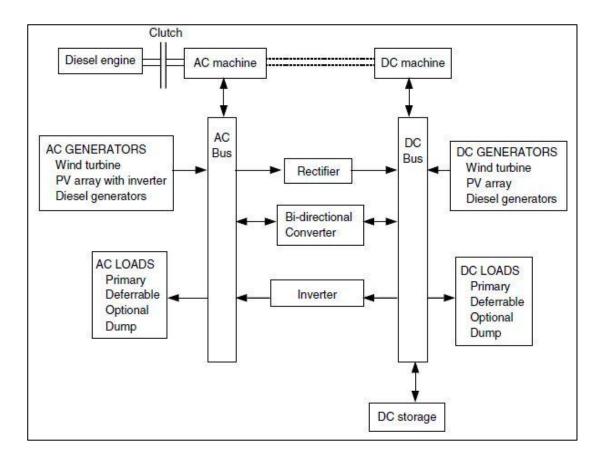

Figure 2-2: HPS possibilities [15]

In a HPS, a diesel power generator acts as a back-up system in circumstances which may render RES capturing components unavailable. The system is usually modified so that the diesel generator is not always required, but in that case other components must be added. There are a number of wind turbines that supply DC power as their principal output. These machines are typically in the smaller size range of 10kW or less. With suitable controls or converters they can support both AC and DC loads. PV panels represent a useful complement to wind turbines in some hybrid power systems. PV panels inherently generate DC power and therefore usually operate in conjunction with storage and a separate DC bus. In larger systems they may be coupled with a dedicated inverter and act as a de facto AC power source in this case. A dump load is used to dissipate excess electrical power in the network. Such an excess could arise during times of high renewable contribution and low load and can lead to power supply instability. There are two types of power conversion functions of particular significance for hybrid power systems: rectifying and inverting, to charge batteries from AC sources or supply AC loads from DC sources, such as batteries and photovoltaic panels.

Most hybrid power systems incorporate a wide variety of control functions. Some control functions are carried out by dedicated controllers that are integral to the system components. Overall system control is accomplished by the system supervisory control (SSC).

A stand-alone HPS consisting of wind and solar PV is a suitable hybrid combination for most applications, taking care of seasonal changes [16]. They also complement each other during lean periods in that they are both seasonal in nature. Figure 2-3 shows a HPS consisting of wind and solar PV and other components.

Figure 2-3: Solar-wind hybrid power system¹

2.2.1 HPS design

There are different configurations of renewable and conventional energy sources being deployed for telecommunication purposes: Diesel-Battery; Solar-Diesel-Battery; Diesel-Battery-Wind; Solar-Diesel-Battery-Wind or Solar-Battery. The configuration of a HPS depends on three factors namely, RES availability, load, and costs (i.e. CAPEX and OPEX) [11]. Thus, the HPS is selected to optimize the available resources vis-à-vis various constraints to improve performance, economy and reliability.

2.2.2 HPS Design Optimization

Optimization of a HPS looks into the process of selecting the components based on NPC, Total Annualized Costs (TAC), and Salvage Costs (SV). The RES components are then sized to provide efficient, reliable and cost effective energy [17]. There are

¹ <u>http://sunfadgroup.com/Wind-Solar%20Hybrid%20System.html</u> (Accessed on 26th March, 2016)

several tools used in hybrid systems design such as dimensioning tools, simulation tools, research tools, and mini-grid design tools although a manual design approach is also possible. However, the manual design approach is both tedious, time consuming, and prone to errors.

A dimensioning tool (also referred to as a sizing tool) is capable of dimensioning HPS system, i.e. for a given energy requirement, this tool can be used to determine the optimal size of each component in the system based search space. Search spaces consists of optional number of components and ratings as specified by the designer. With the simulation tool, as opposed to a dimensioning tool, the designer must specify the nature and size of each component. The tool then provides a detailed analysis of the behaviour of the system. Performing Research and Development (R&D) at component and system level requires a high level of flexibility in the interaction of the components. While traditional simulation tools can perform extensive sensitivity analyses, they generally do not permit the user to modify the algorithms that determine the behaviour and interactions of the individual components and research tools must therefore be resorted to. Mini-grid design tools assist with the design of the mini-grid electrical distribution network[18]. Table 2-1 gives a summary of some of these tools category-wise.

Table 2-1: Overview of simulation tools [18]

2.3 HOMER and NPC

Hybrid Optimization Model for Electric Renewables (HOMER) software has been developed and is continually improved from time to time by National Renewable Energy Laboratory (NREL) [19]. HOMER is primarily an optimization software package which simulates various RES system configurations and scales them on the basis of NPC [20]. HOMER calculates the available renewable power and compares it to the required electrical load. Any constraints on the system imposed by the user are then assessed; e.g. the fraction of the total electrical demand served or the proportion of power generated by renewable sources.

NPC represents the life cycle cost of a system. The calculation assesses all costs occurring within the project lifetime, including initial set-up costs, component replacements within the project lifetime, maintenance and fuel. Future cash flows are discounted to the present. HOMER calculates NPC according to

where Capital recovery factor (CRF) in equation 2.1 is defined as

$$CRF = \frac{i}{1 - [1 + i]^{-t}}$$
.....(2.2)

HOMER assumes that all prices escalate at the same rate, and applies an 'annual real interest rate' rather than a 'nominal interest rate'. NPC estimation in HOMER also takes into account salvage costs, which is the residual value of the power system components at the end of the project lifetime. The salvage value (SV) is given as

$$SV = C_{rep} * \frac{R_{rem}}{R_{comp}} \dots$$
(2.3)

Annual savings are estimated by subtracting the annualized costs from the annualized gains, giving the overall saving or loss for each year. Published payback times for grid-connected small-scale systems range from seven years (IC aided by large rebates) to 11.2 years, 15 years or as high as 30 years [20].

2.4 Summary

Renewable energy is free in nature, continuously replenished, and does not pollute the environment, while reducing dependence on the non-renewable and polluting sources of energy. In addition, use of RES saves funds for the investors. There are various types of RES which have been used over the world successfully. Most of the Telkom Kenya tower systems in the remote areas are powered by diesel generation, although such may be located in RES abundant areas, which is a polluting source. To design a HPS system, information about the RES availability is required. The system is then optimized based on various costs. The final decision is determined from the expected savings to be made by implementing the designed HPS system. This triggered objectives and the order in which they were carried out in this study.

CHAPTER 3: MATERIALS AND METHODS

3.1 Energy demand and renewable resources availability

The starting point in the design phase of the HPS treated in the work was the assessment of the availability of the respective renewable resources at the site. Solar insolation and wind speeds were accessed and sizing of the various components of the HPS then based on the energy demand of the tower and the average RES available on site.

A HPS prototype was assembled and installed at the site for the purposes of measuring the RES potential. The HPS consisted of 50W wind turbine, 20W solar panel and 40AH battery as well the measuring meters. The RES potential was based on the actual percentage of generation from each component over a period of time. After installing the prototype, the respective amount of energy generated from each source was read from the energy meters and noted. This was to represent the actual performance of the system and act as a baseline for similar systems which may be installed at this site irrespective of their ratings.

3.1.1 Load/demand assessment

The energy demand for the tower components was based on the rating of the current energy consuming equipment of the tower system. The total energy consumption in kW was computed and used as the basis for the HPS design. The monthly peak power demand was then used in HOMER as this has to be met continually by the HPS.

3.1.2 Wind Resource Assessment

The data pertaining to the wind resource available at the location was required to estimate the power output [1]. The wind resource data for this project was based on secondary sources which included latest published studies, for the last 15 years, such Kenya Meteorological Department data, and NASA weather data. Actual data collection, using an anemometer, and analysis was performed to verify documented data.

Most secondary sources provide wind speeds measured at different heights above the ground. To draw valid conclusions, the prototype height of 3m above the ground was adopted in the current work and all readings therefore normalized to this height using the wind shear logarithmic law shown in equation 3.1.

$$V_{z} = V_{z_{ref}} \left[\frac{\ln\left(\frac{z}{z_{0}}\right)}{\ln\left(\frac{z_{ref}}{z_{0}}\right)} \right] \dots (3.1)$$

where: V_z is the wind speed at the current height "z" above ground (3 m) $V_{z,ref}$ is the wind speed at the reference height " z_{ref} " $Z_o = 0.01$ m is the roughness length [6]

3.1.3 Solar Resource Assessment

Kenya straddles the equator and therefore generally receives consistently high solar radiation. Solar insolation data in kWh/m² was used to assess the site-specific solar availability and these values then used to determine the amount of photovoltaic energy output [1].

3.2 Hybrid power system design

In the front end, HOMER calculations on size of the wind, solar and battery systems was carried out following an iterative scheme based on the respective average monthly data of the measured RES according to the procedure provided in [4], [20]. Various HPS components were then sourced from various manufacturers and their cost and power characteristics compared.

3.3 Cost-Benefit-Analysis

It is pertinent that economic justification should be made while attempting to optimize the size of integrated power generation systems [4]. The economic analysis of the HPS was performed and the cost aspects taken into account for optimization of the size of the systems. Using the HOMER model developed, various costs, namely, NPC, COE, SV and TAC were computed considering the life period and replacement costs of the individual systems as highlighted in [4], [20].

The HPS configurations in this study consisted of wind energy, solar energy, battery bank, and optimized diesel generator to act as back-up energy source when RES capturing components are not available. These configurations were then modelled and analysed to determine the most viable configuration based on the NPC of the system over its lifetime and diesel fuel consumption. HOMER software assisted the researcher in assessing the technical feasibility of each system design and the NPC of the system. While RETScreen and Hybrid2 software can do simulation just like HOMER, HOMER has the dimensioning capability and thus it was chosen in this project. In addition, it could be accessed for free.

CHAPTER 4: RESULTS AND DISCUSSIONS

4.1 Tower system BTS and Transmission load

The energy consuming equipment for Aitong station as follows:-

The power needed for radio site depends on BTS type, generation, traffic and output power and the power consumption ranges from 1000 -1200 watts for a S222 BTS configuration and power consumption of a microwave radio link depends on capacity and ranges from 200 to 300watts and this is according to manufacturer's specifications. The security and aviation warning tower lights range from 20 to 25 watts according to manufacturer's specifications and the lights works during the night.

The daily average energy consumption of the tower BTS and the transmission load was found to be approximately 36 kWh with an errors of +ve (positive) or -ve (negative) 10%.

The daily average energy consumption of the tower BTS and the transmission load was found to be approximately 36 kWh with an errors of +ve (positive) or –ve (negative) 10%. This was based on the power consumption maintenance monitoring data for Telkom Kenya sites for the last 15 years. This translated to 1.5 kW of power requirements for the tower system. The security lights and aircraft warning light at the top of the tower represented a night-time average load of 50 W as from historic data recorded over a long time by the maintenance technicians at the site. Figure 4-1 shows the hourly BTS load pattern while Figure 4-2 shows the lighting load pattern of the telecom tower as modelled by HOMER software.

Figure 4-1: Hourly BTS load pattern for the tower

Figure 4-2: Hourly lighting load pattern for the tower

4.2 Renewable energy sources availability

RES availability in the study area was categorised into secondary data and actual data. The secondary data was based on the published NASA historical data, Kenya Meteorological Department (KMD) published data from KMD library, and previous studies on the availability of RES in the Aitong area [6], [21][22], [23] and [23]. Actual data was the data collected by use of a prototype HPS installed at the study site. From the analysis of the two sets of data, conclusions on average RES potential were drawn and the HPS designed based on these findings.

4.2.1 Secondary data collection and analysis

4.2.1.1 Wind energy potential

Data collected, documented and published by NASA Data atmospheric centre for the last 35 years for Aitong area, are shown in Table 4-1. These indicate an average wind speed of 4.97 m/s at 50m above ground level (agl) (source: NASA²).

²<u>https://eosweb.larc.nasa.gov/cgi-</u> in/sse/grid.cgi?email=skip%40larc.nasa.gov&step=1&lat=-1.18&lon=35.25&submit=Submit (Accessed on 26th March, 2016)

Month	Average wind speed (m/s)

November	4.76
December	4.49
Average	4.97

Table 4-1: Monthly averaged wind speed at 50 m agl

A study carried out for Ministry of Energy (MoE) Republic of Kenya in 2013 showed that average wind speeds in Narok, where the current site is located, is 5.55 m/s at 40 m height [22].

A study carried out by [23] as shown in Figure 4-3 presents wind data in Kenya which places Narok region in the 4.5 to 5.5 m/s wind speed zone measured at 80 m height.

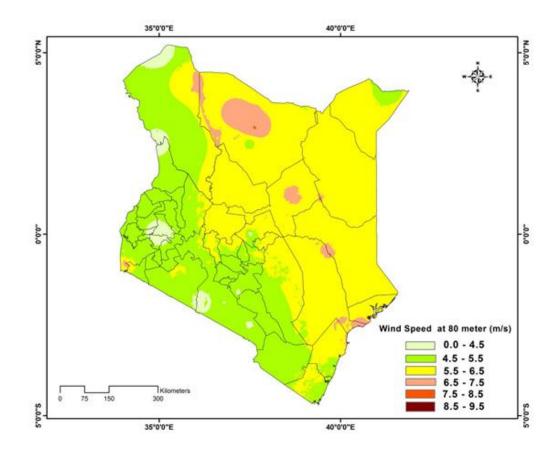

Figure 4-4: Kenyan wind speed map at 80m altitude [23]

A study by [6], [21] shows that the wind energy potential in the Kenyan Rift Valley region stands at 3.36-5.5 m/s measured at 20m above the ground level (agl).

The daily wind speeds as recorded and published by KMD between 1964 and 1980 are presented in Appendix 2. This is the only reliable and well documented data by KMD. The average wind speeds at 0600 GMT is 4 knots (equivalent to 2.06 m/s) while at 1200 GMT it is 9 knots (equivalent to 4.63 m/s) at 10 m above ground level (agl). Table 4-2 shows the summary of the wind speeds extracted from Appendix 2.

	Average wind speed @10m above ground level

Average	5.95

Table 4-4: Monthly averaged insolation incident on a horizontal surface

The daily average solar insolation of 476 langleys (equivalent to $5.54 \text{ kWh/m}^2/\text{day}$) as recorded and published by KMD between 1964 and 1980 are presented in Appendix 2. This is the most reliable documented data. Based on the secondary data, Table 4-5 shows the summary of the solar potential for the site.

Source	Solar power potential

4.2.2 Primary data collection and analysis

4.2.2.1 HPS prototype assembly

Figure 4-5 shows the HPS prototype block diagram while Appendix 3 shows the circuitry of the same. Appendix 4 highlights the specifications of the HPS prototype components.

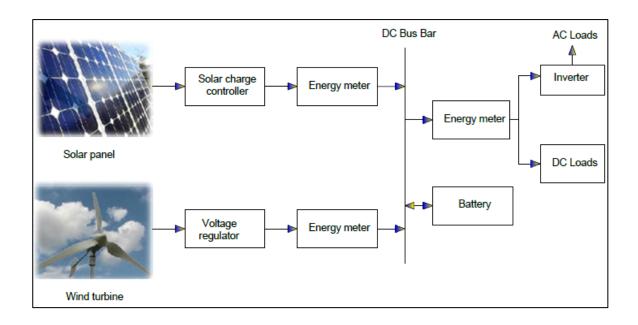

Figure 4-6: Prototype HPS

4.2.2.2 Data analysis

The testing period was divided into seven periods labelled 1 to 7, each covering 21 days as shown in Table 4-6. The full actual data is shown in Appendix 5. After every 21 days, the system was reset for checks and maintenance carried out where necessary. The most important data are the insolation levels and wind speed. The purpose of the consumption loads was to make sure that there was continuous loading of the RES. Figures 4-6 and 4-7 show a representation of the solar insolation and average wind speed for the site respectively. The actual average wind speed for the site respectively. The actual average wind speed for the site is 6.0 kWh/ m^2/day .

4.3 HPS design

The HPS was modelled using HOMER. The RES data was based on NASA data uploaded directly to the software from the NASA website. The optimization was based on various sensitivity analyses including the cost and the available RES.

4.3.1 HPS modelling

The model consists of a XL6R wind turbine, PV, FB10-130 batteries, BDI converter, and an auto sized diesel generator as shown by Figures 4.8-4.15 which represents the HOMER simulation results. Table 4-7 shows the eight (8) best combinations based on NPC (of both CAPEX and OPEX) for various components from the HOMER simulation results. Figures 4-16 to 4-21 shows the designed HPS daily profiles.

			Archi	itecture				Cos	st (KES)		System	Auto Genset

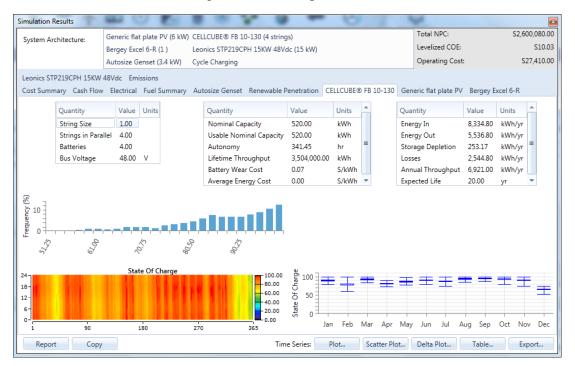

Figure 4-14: Battery operation

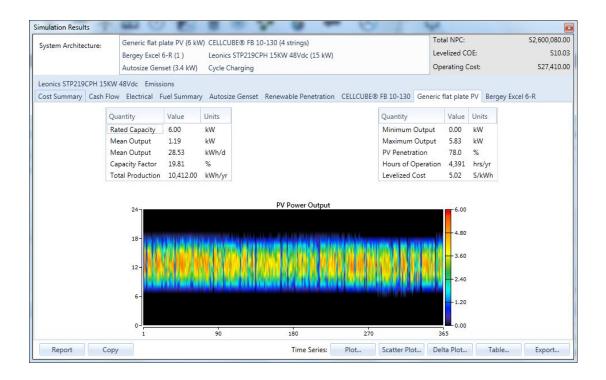

Figure 4-15: PV output

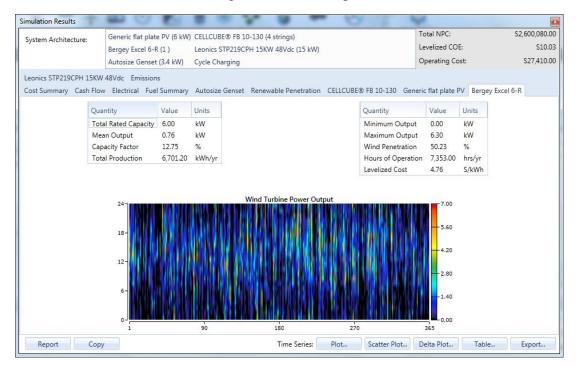

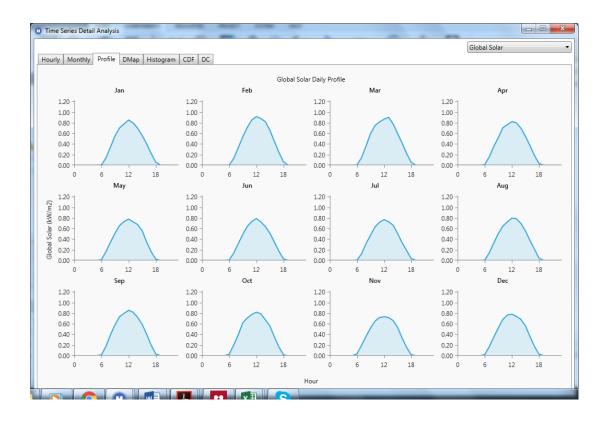

Figure 4-16: Wind turbine output

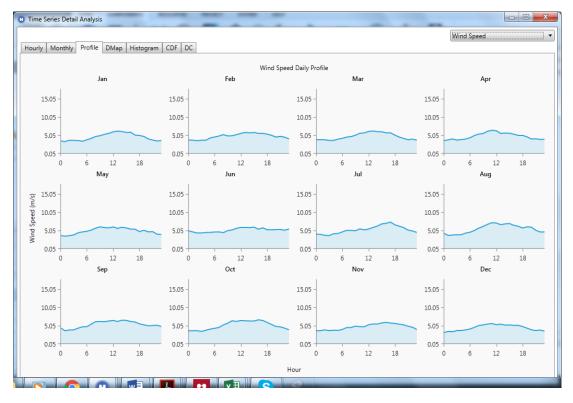

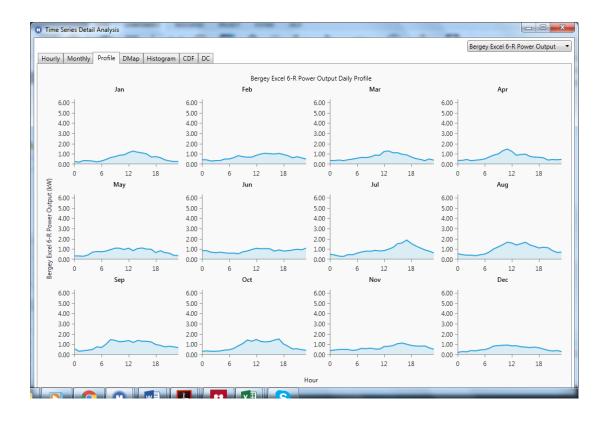

Figure 4-18: Wind speed daily profile

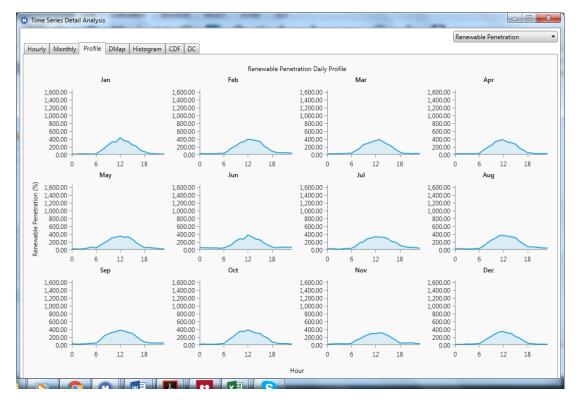

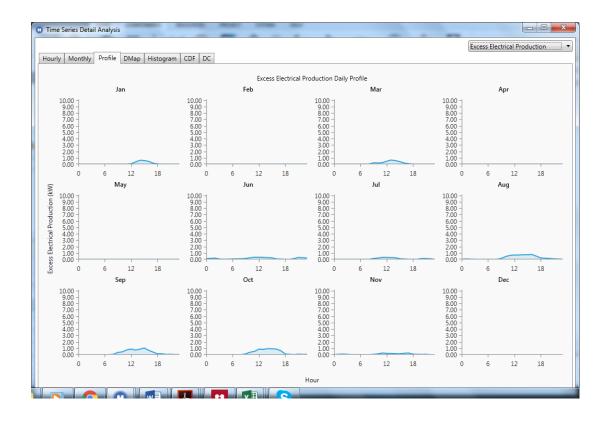

Figure 4-20: RES penetration daily profile

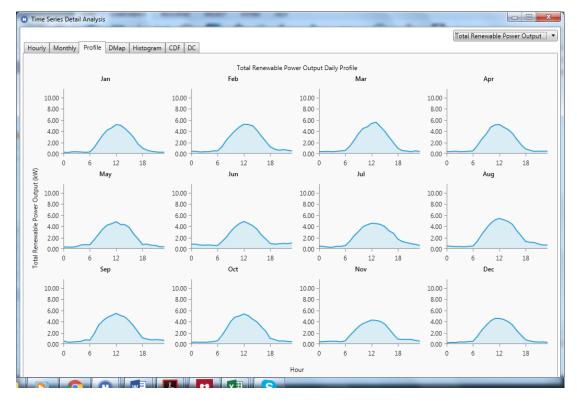

Figure 4-22: Total RES output daily profile

The HPS annual production from the best combination of different components is as shown in Figure 4-11. PV is expected to account for 61%, and the wind turbine to generate the rest of the energy consumed. There will be no production from the Genset and thus, under normal circumstances, this will act as a back-up system in the case of RES or components for capturing RES becoming unavailable.

4.4 Economic viability of the HPS

The various costs involved in this HPS are the CAPEX, OPEX, COE, and the NPC generated by HOMER and used to make the decision on the best combination of various components. These costs are as a result of the current cost of the components and the discounted cost over the whole life of the HPS.

It can be noted from Figure 4-9, which shows the summary of the costs based on the best combination of the HPS components, that a 5% excess energy generation can be expected. The total annual energy generation is expected to be 17,133 kWh with a NPC of KES 2.6 million. A COE (cost of energy) of KES 10/kWh and a total operating cost of KES 437,180. The entire load can therefore be met fully with the two renewable energy resources.

The CAPEX of the current power system in the tower system was estimated as KES 5 million and the annual operating cost (OPEX) as KES 3 million. The breakdown of the O & M is tabulated in Appendix 1. Considering a discount interest rate of 17.5%³, a life-cycle of 15 years and applying Equation (2.1), the NPC of the OPEX is approximately KES 16 million. If an investment of the current system was to be made today, a total of KES 21 million (NPC of OPEX and CAPEX) will be required

³ <u>https://www.centralbank.go.ke/</u> (Accessed on 26th March, 2016)

against a KES 2.6 million for the HPS in this study. Based on the same argument, the COE of the existing system will be much higher than the COE in this study. The current O&M for the existing system is KES 3 million while the O&M for the HPS system is KES 27,410. The net savings if the current system is replaced with the HPS is therefore, KES 2,972,590. Based on this, the return of investment will be approximately 9 months.

CHAPTER 5: CONCLUSIONS AND RECOMMENDATION

5.1 Conclusions

This study has demonstrated that there is sufficient RES at the Aitong site to power the Telkom Kenya BTS system. The RES measured and reported at the site during the testing period compares well with the NASA documented data and other secondary sources consulted during this study. It will be worth noting that data from NASA was used in the design of the HPS since it agreed closely with the collected data. The average wind speed for the site as documented by NASA was 3.33 m/s while the actual average speed as measured during this study was 3.27 m/s. The average insolation by NASA was 5.95 kWh/m²/day against the actual average insolation of 6.0 kWh/m²/day recorded in the study. It can also be concluded that NASA data can be applied at other sites to drive decisions on whether to substitute current power sources with economically efficient source(s) of power.

The design of the HPS system was aided by the use of HOMER. It included sourcing for the costs of various HPS components in the market and analysis of the best combination from a cost perspective. The design also factored in future modification for the tower loads in terms changes in technology. In particular, changes in technology will involve use of power saving BTS equipment. The HOMER optimization model was chosen based on the attractive NPC cost of the system.

The NPC for the current system was found to be KES 2.6 million compared to KES 21 million for the current system employed in the tower system. The COE was found to be KES 10/kWh which is better than the KPLC rate for October, 2015 at KES 21/kWh for other Telkom Kenya similar sites. It should be noted that the cost

analysis in this study did not include the environmental cost and the actual per unit kWh cost is likely to be considerably lower than the calculated cost. The return on investment was found to be favourable at 9 months.

It was noted that the simulation software results varies according to RES components' prices. This is due to the fact that HPS components prices vary from region to region. This does not allow for automatic updates of changes in cost and other characteristics of the various HPS components. Consequently, this was identified as a weakness of HOMER software.

5.2 Recommendations

The following are the recommendations based on the study:

- a) Based on the study, there is a good regime of RES at the study area which can be utilized as a source of power for remotely located tower system.
- b) Finally, it is recommended that mapping of RES in all other sites be carried out to ensure that the best system(s) are selected for each tower system.

Appendix 2: Climatological statistics recorded at Narok Met. Station (KMD)

Appendix 3: HPS prototype circuit

NO:	Component	Specifications/purpose in the system	Number of
1101	component	specifications, pur pose in the system	components
1	Solar panel	20W, 18V, with 1.28 m tower	1
2	Wind	50W, 12V DC, with 3m tower	1
-	turbine		1
		60V 100A Digital LCD Display Voltage, Current, Power, Battery	
		Voltage	
		Analysis:	
		Voltage: (0) V-4V-60V 0.01V (Resolution); Current: 0-100 A	
	Energy	peak 0.01A (Resolution); Power: 0-655.4 W 0.1W (Resolution);	
3	meter(s)	Charge: 0-65 Ah 0.001Ah (Resolution); Energy: 0-655.4 Wh 0.1	3
	ineter(3)	Wh (Resolution); Measurement Update period: 400mS; Signal	
		Sampling Rate: sample/s; Data Queue Sequence time: 2 seconds;	
		In Circuit Resistance: 0.001 Ohms; Operation Current: 7 mA;	
		Auxiliary Power Voltage : 4.0V ~ 60V; Size : 8.3 x 4.7 x 2cm /	
		3.27 x 1.85 x 0.79inch; Display Screen : 1602 STN LCD	
4	Battery	12V, 40AH deep cycle, maintenance free	1
	Solar	Solar Panel Regulator Charge Controller 10A 12V/24V Auto	
5	charge	Switch Safe	1
	controller		
6	Loads	Three 9W DC bulbs and one 11W DC bulb. Total of 38W of DC	4 DC bulbs
U	Louus	loads	1 DC 50105
7	Inverter	30 A inverter	1
8	Bus bar	Twin strip for +ve and –ve sides.	1
