---

**Abstract:** Variation in nutritional and anti-nutritional contents among six finger millet genotypes was determined. Improved finger millet genotypes Gulu-E and FMV-1 from Kenya Agricultural Research Institute, KNE-479 and KNE 1034 from International Crops Research Institute for Semi-Arid Tropics (ICRISAT) and local landraces Ateso and Nyaikuro, were compared. There was no significant ( $p > 0.05$ ) difference in calcium (Ca), iron (Fe) and zinc (Zn) contents among the genotypes. Genotypes Ateso and Gulu-E had the highest crude fat contents while KNE-479 had the lowest. Genotypes KNE-479 and Nyaikuro had the highest crude protein content. Lowest crude protein contents were observed in genotypes Gulu-E and Ateso. Genotype Ateso followed by FMV-1 and Nyaikuro had high isoleucine, leucine, methionine, threonine and cysteine amino acid contents. High levels of phenylalanine were observed in genotypes Nyaikuro and Ateso. Ateso had the highest P-hydroxybenzoic, sinapic and syringic acids, while Nyaikuro had high ferulic and vanilic acids. Except for genotype KNE-479 with highest sinapic acid contents, the ICRISAT developed genotypes had the lowest anti-nutritional contents. Anti-nutrients tannins, vanilic acid and ferulic acid were negatively correlated to Fe and Zn contents. Therefore when selecting finger millet for Fe and Zn the levels of anti-nutritional contents need to be considered.

**Key words;** anti-nutritional contents, finger millet, genotypes, nutritional factors

---

### I. Introduction

Finger millet (*Eleusine coracana*) is an important food and fodder crop in arid and semi-arid lands (ASALs) of Africa and Asia where it performs well than other cereals ([1];[2]). Because of its ability to tolerate drought under poor soil conditions, it is deemed an important crop to increase food security in ASALs ([3]). Among the major food grains, finger millet is one of the most nutritious crops as it contains high quality minerals (calcium (Ca) and iron (Fe)) and amino acids (methionine, an amino acid lacking in the diets of hundreds of millions of the poor who live on starchy foods such as cassava, plantain, polished rice and maize meal); and provides 8-10 times more Ca than wheat or rice ([4]; [5]). Calcium deficiency leading to bone and teeth disorder, Fe deficiency leading to anemia can be overcome by introducing finger millet in our daily diet ([6]). Finger millet also has medicinal attributes used by diverse communities for making special foods for diabetics, gluten-free food for people suffering from celiac disease and weaning foods for infants ([7]). Starch fractions in finger millet are slow in digestion and absorption hence favorable in the diet pattern for metabolic disorders such as diabetes, hypertension, and obesity ([8]).

Maximum utilization of the nutrient potential of finger millet may be limited by the presence of anti-nutritional compounds such as phytates, phenols, tannins and enzyme inhibitors ([6]). Even though they play an important role in biological functions of plants, in human and animals anti-nutritional compounds are partly negative because they reduce the digestibility of nutrients and the absorption of minerals ([9]). They may also inhibit growth as a result of their negative influence on the function of pancreases and the thyroid gland, and can cause pathological alterations in the liver. Tannin compounds affect color, flavor and nutritional quality of the grain and products prepared from it ([10]). Phytic acid complex combine with essential dietary minerals such as Ca, zinc (Zn), Fe and magnesium (Mg) to make them biologically unavailable for absorption. A number of recently improved (bred) genotypes have been developed for drought conditions in Kenya. However, the relationship between genotype and nutritional and anti-nutritional compounds of the genotypes has not been determined. The objective of this study was therefore to determine nutrient and anti-nutritional contents and their relationship among finger millet genotypes.

## **II. Materials and Methods**

### **2.1 Sources of Materials**

Finger millet genotypes were chosen following an on-farm experiment conducted at Katangi location of Machakos County in eastern Kenya. The Katangi farm lies on the grid 01.34133S; 007.64623E with an altitude of 1600 mm (a.s.l). The region is drier and experiences an annual rainfall ranging between 300-650 mm with 40% reliability while evaporation rates ranging between (1800-2000 mm/year) ([11]). Six genotypes from different sources were selected based on their drought tolerance and yield performance during the 2012/2013 planting season. They included improved finger millet genotypes Gulu-E and FMV-1 from Kenya Agricultural Research Institute (KARI), KNE-479 and KNE 1034 from International Crops Research Institute for Semi-Arid Tropics (ICRISAT) and Ateso and Nyaikuro as the local landraces. Genotypes Ateso, Gulu-E and FMV-1 were selected as high yielders while KNE-1034, KNE-479 and Nyaikuro as low yielders. In the field experiment, the genotypes had been put as main plots of a split-plot arrangement in a randomized complete block design, with the treatments replicated thrice.

### **2.2 Preparation of materials**

After harvesting, finger millet was sun-dried for 5 days to a moisture content of 12-13% and to constant weight. The chuff was removed after threshing by winnowing to ensure clean grain that is free from foreign material. A mass of 50g of each sample was weighed and labeled. The samples were then grounded to a fine powder ready for analysis.

### **2.3 Measurement of Variables**

#### **2.3.1 Mineral contents**

Calcium, Fe, and Zn contents were determined on 5.0g finger millet sample which was weighed and oven dried overnight at 110°C. Organic materials from the sample were removed by dry-ashing, then the residue was divided into three replicates (portions) containing 0.1g of each sample. The mineral contents were determined by the procedure of [12].

#### **2.3.2 Proximate composition analysis**

Proximate composition analysis included moisture content, crude protein, crude fat, carbohydrate content, energy content and total ash content and crude fiber.

Moisture content was determined on 5.0 g, in triplicates, samples of finger millet as described by ([13]).

Crude Protein was determined on 0.5g fresh finger millet grain samples, in three replications, by ([12]).

Amino acids in finger millet were determined on samples of 3.0g of finger millet in triplicates using Gas Chromatography- Mass Spectrometry (GC-MS) analytical method ([12]).

Crude fat content was determined on 3.0g weight of finger millet flour samples by a method described by ([13]).

Total carbohydrate contents of raw and processed finger millet cultivars were calculated from the equations described in [14]).

Total energy was determined by calculation from fat, carbohydrate and protein contents using as described in [15] and [12]). Finger millet flour sample of 2.5g, in triplicates, was put in dishes and total ash content was determined by a method described by ([16]).

Crude fiber was determined by digesting 5.0g of finger millet flour in triplicates, as described by [12] and [13]).

#### **2.3.3 Anti-nutritional contents**

Anti-nutritional contents were determined on finger millet grains after they were manually hulled and ground to obtain a fine powder; and six phenolics; sinapic, ferulic, *p*-hydroxybenzoic, syringic, salicylic, *p*-coumaric, and vanillic acids determined by a method described by ([17]).

### **2.4 Data analysis**

The data were subjected to analysis of variance (ANOVA) using Genstat statistical package version 18 and means separated by least significant difference at  $P= 0.05$ . Duncan's multiple range tests was used to compare the means. Correlation tests between nutritional and anti-nutritional contents were done.

### III. Results

#### 3.1 Mineral Contents

Calcium, Fe and Zn mineral contents were not significantly different ( $p > 0.05$ ) among genotypes (**Table 1**). Calcium content had a mean content of 2944mg/kg while Fe and Zn contents averaged 98mg/kg and 16.9mg/kg, respectively.

#### 3.2 Proximate composition

Crude fat and crude protein contents significantly varied ( $p < 0.05$ ), while ash, carbohydrates, moisture, energy and crude fiber contents did not differ among the six finger millet genotypes (**Table 2**). The highest crude fat contents were observed in high yielding genotypes Ateso and Gulu-E. In contrast, the lowest crude fat content was observed in genotype KNE-479. Genotype KNE-479 had the highest crude protein content while genotypes FMV-1, Gulu-E and Ateso had the lowest crude protein contents.

**Table 1: Calcium, Iron and Zinc contents in finger millet genotypes at Katangi in Machakos County**

| Genotypes | Mean of mineral contents in (mg/kg) |                     |                    |
|-----------|-------------------------------------|---------------------|--------------------|
|           | Calcium                             | Iron                | Zinc               |
| Ateso     | 2968                                | 120                 | 20                 |
| Gulu-E    | 3199                                | 33                  | 15.3               |
| FMV-1     | 2875                                | 40                  | 15.3               |

#### 3.3 Amino acids contents

Amino acids contents significantly differed among genotypes ( $p < 0.05$ ) (**Table 3**). Only genotype KNE-479 had the lowest isoleucine contents compared to the others genotypes. Genotypes FMV-1 and Ateso had the highest leucine contents while genotype KNE-479 had the lowest. Genotypes Nyaikuro had the highest lysine contents followed by KNE-1034 while the lowest lysine contents were observed in genotypes KNE-479, Ateso and Gulu-E. The highest methionine contents were observed in genotype Ateso, in contrast, genotypes KNE-479 and Gulu-E had the lowest. Highest phenylalanine contents were observed in genotype Nyaikuro followed by Ateso and FMV-1 while genotype KNE-1034 followed by KNE-479 had the low contents. Threonine contents were highest in genotypes Ateso, Gulu-E and FMV-1 compared to genotypes KNE-1034 and KNE-479 which had the lowest contents. The highest cystein contents were observed in genotypes Nyaikuro followed by Ateso while the lowest contents were observed in genotypes KNE-479 and Gulu-E.

### 3.4 Anti-nutritional contents

Except for tannins, significant differences in all anti-nutritional contents were observed among the genotypes ( $p < 0.05$ ) (Table 4). Tannin contents didn't differ among genotypes. Highest ferulic acid contents were observed in genotype Nyaikuro. Genotype KNE-479 had the lowest ferulic acid content. P-hydroxybenzoic acid content was highest in genotype Ateso and lowest in genotypes KNE-1034. Genotypes KNE-479 followed by Ateso and Gulu-E had the highest sinapic acid contents while the least contents were observed in genotype FMV-1. The highest syringic acid contents were observed in genotype Ateso, while lowest were observed in genotype KNE-1034. Genotypes Nyaikuro and FMV-1 had the highest vanilic acid contents while genotypes Gulu-E and KNE-1034 had the lowest contents.

**Table 4: Variability of anti-nutritional content in finger millet genotypes at Katangi in Machakos County**

| Varieties | Anti-nutritional contents (ug/g) |                    |                       |                     |                    |                    |

### 3.5 Correlations

#### 3.5.1 Correlation of Minerals and Anti-nutritional factors

The correlation between finger millet Ca and all anti-nutritional contents was not significant. There was a significant correlation ( $p < 0.05$ ) between Fe and all the anti-nutritional contents (Table 5). Iron content was positively correlated with P-hydroxybenzoic, syringic and sinapic acids. Negative correlations were observed between Fe and tannin, vanilic and ferulic acids. Iron and ferulic acid had a strong negative correlation. Zinc showed significant correlation with all the anti-nutritional contents. Anti-nutritional contents P-hydroxybenzoic, syringic and sinapic acids had a positive correlation with Zn. A strong positive correlation was observed between Zn and P-hydroxybenzoic acid. Negative correlation was observed between Zn and tannins, vanilic and ferulic acids.

#### 3.5.2 Correlation of proximate composition and Anti-nutritional contents

Correlation between finger millet calorific value and anti-nutritional contents was not significant. However, there was a positive but weak correlation between calorific value and tannins and ferulic acids (Table 6). There was no correlation between crude protein and all the anti-nutritional contents. Carbohydrate content was weak but positively correlated to tannins and syringic acid. Fiber contents had a weak and positive

correlation with vanilic, sinapic and ferulic acid. Even though weak, only tannins were positively correlated to moisture content.

**Table 5: Correlation between anti-nutritional contents and mineral contents in finger millet genotypes at Katangi in Machakos County**

### 3.5.3 Correlation of Amino acid and Anti-nutritional contents

Amino acids leusine, threonine, methionine, phenylalanine and cysteine were not significantly correlated to all the anti-nutritional contents (Table 7). Amino acid lysine was weakly correlated to P-hydroxybenzoic acid, while amino acid isoleusine was negatively and weakly correlated to vanilic acid.

**Table 7: Correlation between amino acids and anti-nutritional contents in Katangi at Machakos County**

|                     | Lysine   | Leusine  | Isoleusine | Threonine | Methionine | Phenylalanine | Cystein  |

## IV. Discussion

### 4.1 Mineral content

Minerals are inorganic nutrients usually required in small amounts from less than 1 to 2500mg per day and their presence is necessary for maintenance of certain physiochemical processes which are essential to life ([18]). In this study the key minerals Fe, Ca and Zn were determined due to their nutritional importance ([6]). All the six varieties analyzed showed presence of Ca, Fe and Zn in variable quantities irrespective of their yield potential and genetic differences. However, all quantities of the three minerals analyzed didn't differ among the finger millet genotypes. Other studies by ([19]) disagree with our findings where a variation among genotypes in the profile of trace minerals was reported. ([19]) attributed the variation among genotypes in minerals contents to differences in ecological conditions from which the finger millet genotypes originated. The results of this study also differ with findings of other workers who reported differences in Ca content among 36 finger millet genotypes ([20]). Lack of variability in mineral content among the genotypes of this study occurred possibly because few genotypes were used or they originated from related genetic pool.

### 4.2 Proximate composition

Proximate composition comprise of biological materials needed by a human beings in major constituents and includes; crude fat, crude protein, carbohydrates, moisture and energy ([6]). Of all the proximate composition analyzed it is crude fat and protein contents that differed among the genotypes. Presence of fat in seeds affects storability and brewing quality of finger millet; more fat content leads to the grain to become rancid ([21]) Therefore the lower the fat content the longer the storage life and better malting properties. Genotypes Ateso and Gulu-E (local landraces) and FMV-1 (improved varieties form KARI) had high crude fat content. It is of interest to note that fat content increased with increase in yield as the above genotypes also were the high yielding genotypes.

([22]) observed finger millet genotypes that were brown in colour had lower protein contents compared to documented white genotypes that are known to have higher protein contents. Even though all the genotypes used for analysis were brown in color in this study, the protein contents among the genotypes significantly differed with improved genotype from ICRISAT and KARI having the highest contents. This variation of proteins could be as a result of genetic improvement in these particular genotypes ([9]).

In this study the local land races had high fat content but a contrastingly low protein. Conversely, the improved ICRISAT genotypes had low fat contents but high protein contents. International Crop Research for Semi-Arid Tropical major works are geared towards improving finger millet for drought tolerance. Part of the improvements is increasing the genes and metabolites identified for drought tolerances which are protein in nature therefore cumulatively elevating protein contents in these genotypes ([25]).

#### **4.3 Essential Amino acid**

Essential amino acids cannot be produced by the body and must be derived from food. Essential amino acids are important for proper functioning of the body; increase muscle mass, regulates blood sugar and helps muscle recover after exercise, supplies the body with energy, enables the synthesis of carnitine, plays an important role in the production of hormones, antibodies and enzymes essential for the synthesis of haemoglobin and glutathione that fights against free radicals among other functions ([24]). In this study the local landrace Ateso followed by the KARI developed genotypes FMV-1 and Nyaikuro had high isoleucine, leucine, methionine, threonine and cysteine amino acid contents. High levels of phenylalanine were observed in genotypes Nyaikuro and Ateso. These suggest that local land races are rich in essential amino acids and that should be taken advantage of in breeding programs. In contrast the improved ICRISAT genotypes were lacking in some essential amino acids though rich in total crude protein.

#### **4.4 Anti-nutritional contents**

Accumulation and variation of anti-nutritional factors is a biochemical response aimed at protecting finger millet against the prevailing harsh abiotic conditions (drought) and biotic stresses (pest's attacks) ([9]). According to ([9]), tannins contents are higher in dark colored varieties followed by brown varieties and least in white coloured varieties. The genotypes used for analysis were all brown in colour and could be the possible reason for lack of variation in tannin contents. Genotype Ateso had the highest P-hydroxybenzoic, sinapic and syringic acids, while Nyaikuro had high ferulic and vanilic acids. Except for genotype KNE-479 with highest sinapic acid contents, the ICRISAT developed genotypes had the lowest anti-nutritional contents. Variation of phytic acid contents observed among the genotypes could be as a result of adaptation of different genotypes to the different prevailing environmental conditions ([4]). ([25]) identified phytic acid as the main organic storage form of phosphate in finger seed grain which is released in high amounts in drought conditions. Based on the genetic adaptability of different genotypes to prevailing drought conditions, varying amounts of phytic acid contents were produced and accumulated in the seed according adaptability. Our observations mirrors to those reported by ([10]) who recorded variation of anti-nutritional factors for the genotypes screened under different ecological conditions.

#### **4.5 Correlations**

Correlation of nutritional and anti-nutritional nutrients showed both positive and negative relations across all the parameters correlated. Anti-nutritional contents were not correlated to Ca, carbohydrates, calorific value, fiber, moisture content and amino acids. Tannins, vanilic acid and ferulic acid were negatively correlated to Fe and Zn. Our results agree with finding from other studies by ([26]) who reported variation in relationship between physiochemical and functional properties in finger millet. Therefore breeders should breed for genotypes with low anti-nutritional contents of tannins, vanilic acid and ferulic acid.

### **V. Conclusion**

Our study revealed that the local landraces of finger millet were rich in fat content; while the improved genotypes were rich in crude protein contents. It was further revealed the local landraces were also rich in

essential amino acids. It was further shown that Fe and Zn contents were negatively correlated to tannins, vanilic acid and ferulic acid.

### Acknowledgements

The authors acknowledge Regional Universities Forum for Capacity Building in Agriculture (RUFORUM) for their financial support to fund this research through the University of Nairobi. We thank Kenya Agricultural Research Institution (KARI) and International Crops Research Institute for Semi-Arid Tropics (ICRISAT) for their collaboration and allowing their materials to be used for this research.
