# TIME AND COST OVERRUNS IN ROAD CONSTRUCTION PROJECTS IN KENYA UNDER KENYA NATIONAL HIGHWAYS AUTHORITY

By Stanley W. Mwawasi

Research Project Submitted in Partial Fulfilment of the Requirement for the Award of the Degree of Master of Business Administration School of Business - University of Nairobi

October 2015

# **DECLARATION**

This research project is my original work and has not been presented for any academic credit in this or any other university.

Stanley W. Mwawasi
D61/70872/2014
Signed
Date
This research project has been submitted for examination with my approval as the university
supervisor.
Signed
Date
Prof. Gituro Wainaina
Department of Management Science,
School of Business
University of Nairobi

# **ACKNOWLEDGMENTS**

I owe my gratitude to all the people who contributed tremendously towards the completion of this research project. Special thanks go to my supervisor and moderator, Prof. Gituro Wainaina and Dr. Muranga Njihia, respectively for their material and moral support. They are outstanding, easy to work with lecturers with whom I shared passionately.

I am thankful to Kenya National Highways Authority (KeNHA) management, private consulting companies and individuals, and private construction companies for responding to all queries and allowing me to access empirical data and information, which enabled completion of this research. It is my desire that the findings from this study will be used to improve Kenya's overall management of our road construction projects.

My gratitude also goes to my loyal Master of Business Administration (MBA) friends and colleagues, at the University of Nairobi for their material and moral support during the period of our study.

Above all, I thank Almighty God for his enduring love.

# **DEDICATION**

Special dedication to my dear wife, Hannah W. Wamwandu; my daughters and sons for their understanding and bearing with my absence during my entire MBA study. This project would not have been possible without their love and unwavering support.

To my father, Robin W. Mwawasi and my mother, Difroda W. Mwawasi, who despite tremendous odds ensured I attended very good schools, hence a firm foundation.

#### **ABSTRACT**

Many projects in developing countries encounter considerable time and cost overruns, fail to realize their intended benefit or are even totally terminated and abandoned before or after their completion. This study sought to investigate the factors that contribute to time and cost overruns in road construction projects in Kenya. The study adopted a multiple case study and was guided by the following specific objectives; to identify variables influencing road construction time and cost overruns in Kenya, to establish the relative importance of these variables and to determine the quantitative impact of time and cost overruns in road construction projects in Kenya. The study utilized both primary and secondary data. Primary data was collected using a semi-structured questionnaire while secondary data was obtained from annual corporate reports, KeNHA database, contract documents, claims reports, project completion reports, expenditure data bases, project progress reports, and donor agency reports on various road projects run by KeNHA. The target population consisted of 24 successfully completed road projects undertaken by KeNHA in the last three fiscal years. A 40 percent random sample (10 projects) was taken from the sampling frame for the study. A 4-point Likert scale was used to measure the output of each item answered by the participants. Descriptive statistics were used to describe (and analyze) the variables numerically. Principal component analysis was applied to cluster the various variables for easy analyzability, which extracted the following factors as the most critical factors causing time and cost overruns; increase in scope of work, delayed payments to the contractor; poor cost control, foreign exchange rate fluctuations, poor or inadequate specifications in the contract, and unpredicted weather. The Relative Importance Indicator (RII) was used to measure the likelihood or recurrence of the variable from the respondent's point of view. According to the RII analysis, 35 variables had a high possibility of recurring in future similar projects. A multiple linear regression model was used to establish the relationship between the various factors and time and cost overruns in the selected road projects. Time overruns constituted the project time extension in months while cost overrun was measured by the total cost deviations from the initial project cost estimates. Increase in scope of work can be considered to have been the lead factor in contributing to time and cost overruns on the road projects. The other factors in order of significant were delayed payments to contractors, poor or inadequate specifications in the contract, foreign exchange rate fluctuations, unpredictable weather and poor cost control mechanisms. At macro-level, the study recommends that policy makers both at county and national level formulate strategies geared towards mitigating the impact of these factors given the fact that most of them have a high chance of recurring in future road projects. At the micro-level, contractors, consultancies, and other stakeholders need to do proper definition of project scope and apply modern project management tools given the fact that increase in scope of work is a lead factor in the factor contributing to time and cost overruns on road projects. At the preliminary stages, enough material and time resource's should be committed to ensure that adequate feasibility studies are conducted to avoid duality. The study was limited to the extent that; a study of this magnitude should include a survey of sizeable number of road projects over a wider time span of, say 10 years. On the other hand, the study period was a-bit short for a study of this nature and the fact that some of the respondents were non-committal posing major challenge in the field during the data collection. Studies involving confirmatory factor analysis will need to be carried out to further test the model so established and to confirm the findings of this study. Having identified the factors causing time and cost overruns in road projects in Kenya, there is need for further research to focus on the critical success factors in the implementation of road construction projects in Kenya.

#### CHAPTER ONE: INTRODUCTION

#### 1.1 Background of the Study

The increasing complexity of infrastructure projects and the environment within which they are constructed place greater demand on construction managers to deliver projects on time, within the planned budget and with high quality. In many developing countries, major construction activities account for about 80 percent of the total capital assets, 10 percent of their Gross Domestic Product (GDP), and more than 50 percent of the wealth invested in fixed assets. In addition, the industry provides high employment opportunity, probably next after agriculture (Ofori, 2006).

Despite the construction industry's significant contribution to the economy of developing countries and the critical role it plays in those countries development, the performance of the industry still remains generally low (Enshassi, 2008). Studies over the past 20 years reveals a trend of rising cost of construction input resources (Osei-Tutu, 2008) and this trend is expected to continue because the factors responsible for the increased cost trend remain the same. In Africa, the combined prices of labour and materials have increased by 1,229 percent between 1997 and 2010 (Ghana Statistical Services, 2010).

According to Idoko, 2008) many projects in developing countries encounter considerable time and cost overruns, fail to realize their intended benefit or even are totally terminated and abandoned before or after their completion. Moreover, the development of the construction industry in developing countries generally lags far behind from other industries in those countries and their counter parts in developed nations. Generally, construction industry in developing countries fails to meet expectations of governments, clients and society as a whole (Ofori, 2006; & Jekale, 2004).

In Kenya, major road projects have a history of problems; cost overruns, delays, failed procurement, or unavailability of private financing is common yet most overruns are foreseeable and avoidable with the right legal and institutional frame works. Researches on construction projects in some developing countries indicate that by the time a project is completed, the actual cost exceeds the original contract price by about 30 percent (Bruland & Mahamid, 2011). Risk is also under-managed in the later stages of infrastructure projects,

destroying a significant share of their value. Apart from causing budget overruns, it also results in uncertain cost-benefit for decision-making (Jenpanitsub, 2011).

Cost overrun of transport projects is one of the most important problems in transport planning. Apart from causing budget overruns, it also results in uncertain cost-benefit for decision-making. Past empirical findings confirms that cost overrun problem is a global phenomenon and the average cost overruns in rail projects are always higher than in road projects. Although, risk in construction has been the object of attention because of time and cost overruns associated with construction projects, few studies have focused on factors leading to construction risks and failure of road projects in Kenya, hence this study.

#### 1.1.1 Time and Cost Overrun

Time overrun is defined as the extension of time beyond planned completion dates traceable to the contractors (Kaming, Olomolaiye, Holt & Harris, 1997). Delays are incidents that impact a project's progress and postpone project activities; delay causing incidents may include weather delays, unavailability of resources, and design delays. In general, project delays occur as a result of project activities that have both external and internal cause and effect relationship (Vidalis, Allinson & Hayes, 2002).

Choudhry (2004) and Chan (2001) defined the time overrun as the difference between the actual completion time and the estimated completion time. It is measured in number of days. Project delays are those that cause the project completion date to be delayed (Al- Gahtani & Mohan 2007). From above, time overrun is defined as the time increased to complete the project after planned date, which is caused by internal and external factors surrounding the project. In construction, the word "delay" refers to something happening at a later time than planned, expected, specified in a contract or beyond the date that the parties agreed upon for the delivery of a project (Pickavance, 2005). Lo, Fung and Tung (2006) define delay as the slowing down of work without stopping construction entirely and that can lead to time overrun either beyond the contract date or beyond the date that the parties have agreed upon for the delivery of the project. Syed, Azhar, Castillo and Kappagantula, (2002) classify delays into non-excusable delays, excusable non-compensable delays, excusable compensable delays are delays caused by

factors that are not foreseeable, beyond the contractor's reasonable control and not attributable to the contractor's fault or negligence. Compensable excusable delays are excusable delays, suspensions, or interruptions to all or part of the work caused by an act or failure to act by the owner resulting from owner's breach of an obligation, stated or implied, in the contract. Concurrent delays occur when both owner and the contractor are responsible for the delay.

Causes of delays have been identified in various parts of the world such as Malasyia, Saudi Arabia, Jordan, Kuwait, Hong Kong and Thailand (Sambasivan & Soon, 2007; Al-Kharashi & Skitmore, 2008; Al-Momani, 2000; Kumaraswamy & Chan, 1998; Noulmanee, Wachirathamrojn, Tantichattanont & Sittivijan, 1999). The results reveal that there are differences and similarities as to the causes of delays. A degree of change can be, and to a certain extent should be, expected in construction, as it is difficult for clients to visualize the end product that they procure. Cost overrun is also known as "change orders". Cost overrun is defined as the deviation from the amount agreed, as per the contract sum, divided by the agreed original amount of the contract (Zawawi, Azman, Shamil & Kamar, 2010).

Cost overrun is, thus an excess of actual cost over budget and is also sometimes called "cost escalation" cost increase," or "budget overrun (Zhu, Pang & Khan, 2004). Cost overrun is defined as the change in contract amount divided by the original contract award amount. This calculation can be converted to a percentage for ease of comparison (Jackson 1990). Choudhry (2004) defined the cost overruns as the difference between the original cost estimate of project and actual construction cost on completion of works of a commercial sector construction project. According to Jahren, Curtis and Weber (1990), on their research on predictors of cost overrun rates, they found the following factors to influence the cost overrun rates; the size of the project, the difference between lowest bid and engineer's cost estimate, the type of delivery method, the level of competition, quality of contract documents, and the nature of interpersonal relations on the project.

According to Lyneis, Ptero and Tang (2010), problems of cost and schedule overrun on projects have persisted for decades, in spite of numerous advances in the field of "project management". In the 1950s, the static network modeling approaches Program Evaluation and Review Technique (PERT) and the Critical Path Method (CPM) were developed. These have

continued to evolve with the addition of probabilistic parameter estimates and integration with resource loading assessments. Finally, teaming, concurrent engineering, and the recognition and emphasis on "soft" and people factors have emerged as methods of enhancing project performance.

#### 1.1.2 Kenya National Highways Authority

The KeNHA is responsible for the management, development and maintenance of national roads. The Kenya Roads Act, 2007 Section 22(1) empowers KeNHA to construct, maintain, operate, improve and manage the roads under its jurisdiction. The roads that fall under KeNHA are classified as A, B and C. The KeNHA recognizes that road development is not only road construction and maintenance alone, but in the broader sense includes the management and protection of road reserves. The KeNHA is an autonomous road agency, responsible for the management, development, rehabilitation and maintenance of international trunk roads linking centres of international importance and crossing international boundaries or terminating at international ports (class A road), national trunk roads linking internationally important centres (class B roads), and primarily roads linking provincially important centres to each other or two higher-class roads (class C roads). Besides roads, KeNHA has 13 weighbridges, which are used to enforce the traffic regulations in the ferrying of goods across the country and the greater East African region.

#### 1.2 Research Problem

The successful execution of construction projects, keeping them within estimated cost and the prescribed schedules primarily depends on the existence of an efficient construction sector capable of sustained growth and development. Consequently, the iron triangle (cost, time, and quality) is used to measure the project performance and success. Generally, the success measure for a project is defined by completing it within specified cost, time and quality. However, the construction industry is full of projects that were completed with significant cost deviation (Amhed, Zahara & Juma, 2010). Since independence, the imperative to scale up infrastructure and improve the competitiveness of the Kenyan economy has been constrained by construction cost and time overruns. A list of 24 successfully completed road projects undertaken by KeNHA in the last three fiscal years indicating variances in time and cost during project implementation is presented in Appendix III.

The Kenya Vision 2030 aims to transform Kenya to a middle-income country by 2030. The government recognizes that the attainment of Vision 2030 will depend heavily on the quality of the road infrastructure through the reduction of transport costs, improvement of accessibility and road safety. The centrality of the road infrastructure in the Vision 2030 and the heavy annual budgetary allocations to the sector, underscores the need to investigate the time and cost drivers that contribute to time and cost overruns. Financial resources are so scarce in developing countries like Kenya, hence time and cost related issues in Kenya's construction industry are sensitive issues. Therefore, carrying out a research in this area will have a paramount importance. Identification of causes of cost overrun is a prerequisite to minimize or to avoid cost overrun in the construction industry.

A number of studies have been carried out on construction time and cost overruns. Kagiri (2005) in his study of time and cost overruns in power projects in Kenya outlined underlying factors that contribute to time and cost overruns. He identified eight underlying factors including; improper project planning, resource planning, interpretation of requirements, works definition, timeliness, government bureaucracy, and risk allocation as having significantly contributed to time and cost overruns in the projects. While his study provided vital insights into the subject of time and cost overruns, it was conducted in a different study context.

Mahamid (2011) investigated the statistical relationship between actual and estimated cost of road construction activities based on a sample of 100 road construction projects awarded in the West Bank in Palestine. The findings revealed that the average cost deviation in the investigated activities was as follows; earthworks -15.7 percent, base works 12.9 percent, asphalt works 18.5 percent and furniture works 36.4 percent. His findings, however fell short of investigating the cost drivers responsible for the deviation between actual and estimated cost.

Studying the significant factors that cause delay of construction projects in Malaysia, Alaghbari, Kadir, Salim & Ernawati (2007) used four categories for analysis, namely contractor, consultant, owner and external. As far as causes related to contractor actions were concerned; financial problems, shortage of materials and poor site management were ranked among the top three. Owner causes included delayed payments, slow decision-making and

contract scope changes. The top three consultant causes were poor supervision, slowness to give instructions and lack of experience. Finally, external causes of delay included shortage of materials, poor site conditions and lack of equipment and tools in the market.

Anzinger and Kostika (2015) carried out a cross-sect oral analysis of large projects in Germany based on a database of 170 cases (119 finished, 51 unfinished projects) of projects between 1960 and 2014, and found out that there were significant variations in infrastructure project outcomes across sectors in Germany. The energy and Information and Communication Technology (ICT) sectors especially were facing significant cost overruns, with 136 percent and 394 percent on average for finished projects, respectively. In building and transportation, average cost overruns are lower, at 44 percent and 33 percent. By selecting specific examples, and by drawing attention to the most successful and most unsuccessful infrastructure projects, the study summarized possible explanations for this variation and offered recommendations for better management of large-scale public infrastructure projects.

While a-lot of literature exists on construction time and cost overruns, literature on construction time and cost overruns is limited to the developed world with just a few focusing on Kenya. Despite the fact that road project time and cost overruns create a significant financial risk to the government with a history of road construction full of projects that were completed with significant cost overruns, literature on the subject of road construction time and cost overruns in Kenya remains scanty. It is against this backdrop, the current study sought to assess factors that contribute to time and cost overruns in road construction projects in Kenya. The study aimed at answering the following research question; what factors cause time and cost overruns in road construction projects in Kenya?

## 1.3 Research Objectives

The general objective of this study was to determine the time and cost overruns in road construction projects in Kenya under KeNHA, whereas the specific objectives were to:

- (i) Identify variables influencing road construction time and cost overruns in Kenya,
- (ii) Establish the relative importance of these variables, and
- (iii) Determine the quantitative impact of time and cost overruns in road construction projects in Kenya.

#### 1.4 Value of the Study

Identifying the occurrences of time and cost overrun in public construction projects in any country is important before identifying its causes. In this regard, the findings of the this study will provide vital information to the roads and infrastructure ministry and allied agencies on improved cost control and monitoring measures that should be implemented throughout road project stages in Kenya in their quest to mitigate the problem of cost overruns. The level of performance of cost overrun will assist the professionals and the public officials to become aware of the severity of the problem of time and cost overrun in road construction projects in Kenya.

The study findings will equally benefit the private sector particularly in this era when the Kenya government is encouraging public-private partnerships in mega construction projects in the country. For instance, this study will provide insights into the implementation of quality and value management techniques to ensure that the designs adequately cover what the client brief entails. The study will provide backstopping for future scholars on the subject of time and cost overruns in road projects in Kenya. From the recommendations for further studies, this study will identify areas that require further investigation in the dynamic and evolving nature of construction time and cost overruns not only in Kenya but across Sub-Saharan Africa.

#### CHAPTER TWO: LITERATURE REVIEW

#### 2.1 Introduction

This chapter reviews theoretical and empirical literature from past studies on the subject of time and cost overruns. The chapter focuses on; the theoretical framework of the study, the empirical literature review, conceptual framework of the study and finally a summary of the literature review.

#### 2.2 Theoretical Framework

This study will be informed by the following theories; Construction Management Theory (CMT), Transformation-Flow-Value Theory (TFVT) and Planning Theory (PT). Each of these theories is discussed here below with respect to cost and time overruns.

## 2.2.1 Theory of Construction Management

Advanced by Milan and Bennett (2012) CMT provides a "rigorous theory" based on a "tool kit of concepts and relationships" that will improve the efficiency and quality of "construction products". The distinction between the conventional approach of CMT, where contractors deliver projects, and the idea of companies producing a product is an important element in the thinking behind the theory proposed here. Following that intention they identify and define the concepts needed to understand CMT. Radosavljevic and Bennett (2012) self-consciously developed their theory without drawing on general management theories, rather wanting to base their ideas on construction industry projects and practice, which makes these definitions extremely important to their CMT and to the understanding of that theory.

The CMT is critical in road construction project management since it focuses on the concepts, construction products, processes, organizations, interactions, relationships, and learning and performance that constitute the successful project management principles. The theory, thus presents a model by which project managers can put in place critical success factors including communication, feedback lops, and how well established relationships are (called internal) or not (called boundary relationships).

#### 2.2.2 Transformation-Flow-Value Theory

Application of new production philosophy to construction production theory has developed into TFVT (Koskela, 2000). This is a theory that draws on the management literature and history as its base, and its origins are covered in Koskela (2000), where the roots of Lean Construction (LC) in production theory are explored. Koskela, Ballard and Tommelein (2002) argued that what is needed is production theory and related tools that fully integrate the transformation, flow and value concepts. As a first step toward such integration, we can conceptualize production simultaneously from these three points of view however; the ultimate goal should be to create a unified conception of production instead.

The relevance of TFVT to road project management emanates from the fact that ideas and methods of LC in particular offer an alternative to management theories. There are three reasons apart from the usefulness of conceptualizing production processes in a discipline traditionally preoccupied with practical matters. First, LC was prior to Radosavljevic and Bennett (2012), the only theory of production to have been developed specifically for the construction industry. Therefore, it provides insights into the range of processes that are involved, based on theory, that lead to propositions that can be tested by application to building and construction projects. The many case studies that have been published about LC over the years are all tests of the theory and practice of LC. These tests now add to a substantial body of evidence for the effectiveness of LC in a wide range of settings.

#### 2.2.3 Theory of Planning

The term last planner refers to the hierarchical chain of planners, where the last planner acts at the interface to execution. Thus, this method concentrates on the detailed planning just before execution, rather than the whole planning process. The method of last planner distinguishes planned tasks according to can, should and will modalities. The tasks pushed from the higher planning levels belong to the 'should' category. In look-ahead planning (with a time horizon of three to four weeks), the prerequisites of up-coming assignments are actively made ready; they are transferred to the 'can' category. This, in fact is a pull system (Ballard 1999) that is instrumental in ensuring that all the prerequisites are available for the assignments. In conventional project management, the plan pushes tasks to execution; only the 'should' category is recognized.

The PT is relevant to construction project management given the fact that the model enables project managers mitigate the risk of variability propagation to the downstream flows and the tasks reducing the need for large material buffers on site. The last planner effectively combines the control and the improvement to fight back against variability and the waste caused by it. Thus, last planner combines the flow and the transformation view in short term planning, execution and control.

## 2.3 Empirical Literature Review

Research conducted by Azis, Memon, Rahman, Latif and Nagapan (2012) focused on the objective of assessing the level of effectiveness of various cost management techniques implemented in large construction projects in South Malaysia. The results of the study showed that the most effective technique of cost management was cash flow forecasting, tender budgeting/estimating, and an elemental cost plan. Caruthers, Kuotcha MaCcaffer and Edum (2008), however described a cost estimate as an approximation. Therefore, cost estimations require the utmost accuracy in order for clients to ensure that they have sufficient funds to execute the projects without delays due to underestimations (Kaliba, Muya & Mumba, 2010).

Caruthers et al. (2008) stated that the management of costs begins with the financial feasibility study, progresses through all the costs that are required to purchase all the resources needed by the project, through to using cost control to ensure that all work that is done is properly completed. The cost implications of scope creep need to be rigorously controlled by way of formal variation orders (Caruthers et al., 2008).

Kagiri (2005) in his study based in Kenya about the factors of time and cost overruns in power projects found that Kenya was also not a stranger to the recurrence of cost overruns in their projects. The projects experienced time and cost overruns at the same time, but cost overruns on the projects ranged from 9.4 percent to 29 percent. The crucial factors that contributed to overruns in the power projects were contractor inabilities, improper project preparation, resource planning, and interpretation of requirements, definition of works, timeliness, government bureaucracy, and risk assessment.

Kaming, et al. (1997), studied 31 construction projects in Indonesia and found that from a contractor's point of view, cost overruns were mainly caused by inaccuracy of material take-off, increase in material costs and cost increase due to environmental restrictions. Studying the cost overruns and delays on groundwater projects in Ghana, Frimpong, Oluwoye & Crawford (2003), contractors found that late monthly payments from clients were the most important cost and time delay factors, with clients ranking poor contractor performance as the most important cost and time delay factor.

Mansfield, Ugwu & Doran (1994) studied the performance of transportation infrastructure projects in Nigeria and concluded that material price fluctuations, inaccurate estimates, project delays and additional work contributed most to cost overruns. In a fourth study on construction projects in Nigeria by Elinwa & Buba (1994), found that cost of materials, fraudulent practices and fluctuations in materials prices were the main cause of cost and time overruns. Baloyi and Bekker (2010) found that the most significant factor causing cost overruns due to client action was additional work or changes to work.

Supplementing their research on the causes for cost overruns, Kaming et al. (1997) found that design changes, materials shortage and inadequate planning were the most significant contributors to time delays on construction projects. Similarly Sambasivan and Soon (2007) categorized their findings into client, contractor and consultant categories, with all three categories listing poor site management, inadequate contractor experience and poor subcontractors among the top five causes for time delays on construction projects. Assaf, Al-Khalil & Al-Hazmi (1995) used 56 questions in three categories, namely owner, architects/engineers and contractors, to determine the main causes of delays on large building projects in Saudi Arabia. Their survey showed that contractors believed that preparation of shop drawings, delays in contractor's progress and payment by owners were the most important factors contributing to time delays.

Flyvbjerg, Bent and Lund (2009) study provided a clear indication of the severity of time and cost overruns in large infrastructure projects by deducing that over-budgeting and overtime occur repeatedly. Furthermore, explanations of project under-performance in terms of optimum bias and strategic mis-representation lead to high failure rates for projects as a consequence of flawed decision-making. Love (2012), in a study undertaken in Australia to

determine the probable costs of rework, confirmed that the rate of cost overruns for construction projects ranged from a maximum of 244 percent to a minimum of -84 percent (cost under-run). In brief, of the 218 projects assessed by Love (2012), 79 percent of them experienced total rework costs of less than 16 percent.

Cantarelli, van Wee, Molin & Flyvbjerg (2012) indicated that the magnitude of cost overruns on construction projects in the Netherlands did not differ from that of other countries as they highlighted the range of cost overruns, of -40.3 percent to 164 percent. The data implied that an average cost overrun of 16.5 percent. Mahamid (2013) conducted an investigation into the effects of project's physical characteristics on the cost deviation of 74 road constructions in Palestine. In the analysis of cost under-estimation based on the project's category, the study showed that small projects have the highest average of cost under-estimations of 24.9 percent while large projects have the largest average of 15.9 percent.

Time and cost are considered to be the most crucial factors that contribute to the success of a project, and in reality are the only factors on which everything hinges, and are the most critical factors in the decision on whether a project commences or is shelved. Azhar, Farooqui and Ali and Kamaruzzan (2010) concluded that cost performance of construction projects in Malaysia was a critical issue in that country and the recurrence of this problem indicated a need for research to clarify what should be done to mitigate the said problem.

Farooqui, Hussain, Umer and Lodi (2012) confirmed that the factors affecting costs in Pakistan are the most crucial criteria for assessing the success of a project. In their study, they reached the conclusion that poor project management drawn from (management factors) was the key factor affecting the construction costs; this showed that the project manager and his/her teams were in urgent need of improving the performance graph as far as the construction industry of Pakistan was concerned. Poor performance of work (management factor) was the third most crucial factor with a definite potential for affecting the construction cost. The top three location factors were political unrest in the area, followed by remote location and unforeseen ground conditions (Ali & Kamaruzzan, 2010).

#### 2.4 Summary of the Literature Review

The literature reviewed covered the problem of time and cost overrun and shows that it is a problem in developing countries. More importantly, literature on problems of cost overrun in

the context of Kenyan projects has been examined. Recent literature has also revealed that professionals in the construction industry at large, see this problem recurring more and more frequently. A summary of the key literature reviewed is presented in Table 2.1 below.

#### 2.5 Conceptual Framework

In order to investigate research questions, the conceptual framework as shown in Figure 2.1 was adopted. The dependent variable was time and cost overruns, measured by the percentage deviation from the initial project time and cost estimates. The independent variables were the factors that cause time and a cost overrun in road construction projects in Kenya.

Figure 2.1 Conceptual Framework

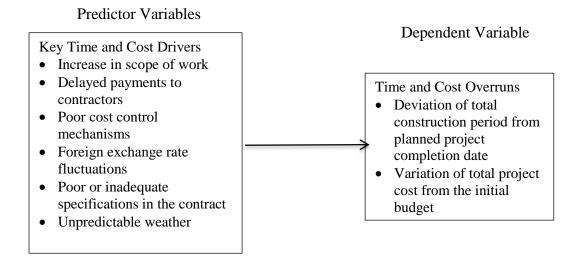

Table 2.1 Summary of Literature Review

Author	Study	Objectives	Methodology	Findings
Ramabodu and Verster (2010)	Identifying causes of cost overruns and effective cost control measures of public projects in Free State Province (FSP) – South Africa	<ul> <li>Identify causes of cost overruns and associated remedial measures for use in South African construction</li> <li>Identify causes of cost overruns in public sector projects in FSP</li> <li>Determine frequency of cost overruns among public sector projects in FSP</li> <li>Ascertain if rate of cost overrun occurrence constitutes performance problem in FSP</li> </ul>	Multiple-case study	Changes in scope of work on site, incomplete design at the time of tender, contractual claims (extension of time with cost), lack of cost planning and monitoring of funds, and delays in costing variations and additional works cause delays

#### CHAPTER THREE: RESEARCH METHODOLOGY

#### 3.1 Introduction

Scandura and Williams (2013) refers research methodology as a systematic way to solve a problem. The literature review explored and provided sources, which articulated methods for the data collection, analysis and exposition, with respect to the objectives of the research. The following section deals with general description of the research strategy adopted for this study as well as a rationale for the methodology. The key topics in this chapter include research design, data collection, sample size, questionnaire design and data analysis.

#### 3.2 Research Design

Kothari (1990) argues that research design is the conceptual structure within which research is conducted; it constitutes the blueprint for the collection, measurement and analysis of data. As such, the design includes an outline of what the researcher will do from writing the hypothesis and its operational implications to the final analysis of data.

The study adopted a multiple case study; a multiple case study enables the researcher to explore differences within and between cases. The goal is to replicate findings across cases and because comparisons will be drawn, it is imperative that the cases are chosen carefully so that the researcher can predict similar results across cases, or predict contrasting results based on a theory (Yin, 2003). Examples of studies that have employed multiple case studies include Campbell and Ahrens (1998) 'Innovative Community Services for Rape Victims: An Application of Multiple Case Study Methodology and Kagiri (2005), 'Time and Cost Overruns in Public Sector Power Projects in Kenya: A Case Study of Kenya Electricity Generating Company Limited'. Tripsas and Gavetti's (2000) in-depth case study of the Polaroid corporation. Case studies give the researcher not only the possibility to describe certain relationships, but also to test theory for a special setting.

#### 3.3 Population and Sampling Design

Snow and Thomas (2013) define a population as an aggregate of all that conform to given characteristics. The target population consisted of 24 successfully completed road projects undertaken by KeNHA in the last three fiscal years (See Appendix III). A 40 percent random sample of 10 projects was taken from the sampling frame for the study. According to Mugenda

and Mugenda (2003), a representative sample is one, which is at least 10 percent of the population, thus the choice of 40 percent was considered as representative.

A sample design is a definite plan for obtaining a sample from a given population. It refers to the technique or the procedure the researcher would adopt in selecting items for the sample (Kothari, 2011). Three respondents were selected from each of the projects consisting of the project manager, a representative from the consultant agency and the main contractor. The selection was based on the time available for conducting the research work and the reliability of the respondents, so that the overall research work would indicate the reality of the situation.

#### 3.4 Data Collection

Both secondary and primary data were utilized in the study. According to Kothari (2011) primary data are those, which are collected afresh and for the first time and thus happen to be original in character. Primary data was collected using a semi-structured questionnaire divided into three parts (see Appendix II). Part A consisted of open-ended questions aimed at obtaining demographic information of the respondents and part B examined objective one, two and three aimed at identifying factors influencing road construction time and cost overruns, to establish the relative importance of these factors, and determining the quantitative impact of time and cost overruns, respectively. In this part, the respondents were required to identify factors, which they perceived to have contributed to time and cost overruns by responding to a Likert scale from 1 (not important) to 4 (very important). Part C of the questionnaire aimed at covering emerging variables that may have risen during the study.

Secondary data was obtained from annual corporate reports, KeNHA database, contract documents, claims reports, project completion reports, expenditure databases, project progress reports, and donor agency reports on various road projects under KeNHA. Secondary data was used to evaluate magnitude of time and cost overruns and relationship between time and cost overruns and the successful completion of road construction projects undertaken by KeNHA.

#### 3.5 Data Analysis

The data was analysed using descriptive statistics, Principal factor component analysis and multiple linear regression analysis as illustrated in Table 3.1.

Table 3.1 Summary of Research Methodology

Objectives	Data	Analyses
Identify variables influencing road construction time and cost overruns in Kenya	Primary data	Descriptive statistics Principal component factor
Establish the relative importance of these variables	Primary data on the ranking of the various factors contributing to time and cost overruns	Relative importance index
Determine the quantitative impact of time and cost overruns in road construction projects in Kenya	Secondary and primary data	Multiple linear regression

## CHAPTER FOUR: DATA ANALYSIS, FINDINGS AND DISCUSSIONS

#### 4.1 Introduction

This chapter presents the findings of the study in investigating the factors that cause time and cost overruns in road construction projects in Kenya, which was based on the following specific objectives to identify variables influencing road construction time and cost overruns in Kenya; to establish the relative importance of these variables; and to determine the quantitative impact of time and cost overruns in road construction projects in Kenya. Data was analyzed using Statistical Package for Social Sciences (SPSS) in-order to determine the factors that cause time and cost overruns. Mean scores, standard deviations, coefficients of variation and multiple linear regression analysis were used to describe and infer the findings.

# 4.2 Demographic Characteristics of the Respondents

Thirty questionnaires were mailed to potential respondents that participated in the implementation of one or more of the road projects. Twenty eight questionnaires were returned representing a response rate of 93 percent. This response rate was sufficient and representative and conforms to Mugenda and Mugenda (2003) stipulation that a response rate of 50 percent is adequate for analysis and reporting; a rate of 60 percent is good while a response rate of 70 percent and over is excellent. Of these 10 (35.7 percent) respondents were from the project management team, a similar number from the consulting agency and eight (28.6 percent) questionnaires were received from the main contractors.

The demographic characteristics of the respondents included respondent's distribution on the projects, position/designation in the respective projects, academic and professional qualifications and working experience. The study sought to investigate the spread of the respondents across the various road construction projects under this study and the results are presented in Table 4.1 below.

From Table 4.1, it is clear that the number of respondents was the same from each of the projects (10.7 percent) other than Timboroa to Eldoret and Kendu-bay to Homa-bay with 7.1 percent respectively. This implies that the sample was representative enough to capture reliable data for the study.

Table 4.1 Respondents Distribution on Projects

Project	`	Percent
Valid Eldoret to Webuye	3	10.7
Timboroa to Eldoret	2	7.1
Marsabit to Turbi	3	10.7
Kendubay to Homabay	2	7.1
Homa Bay to Mbita	3	10.7
Sotik to Ndanai	3	10.7
Londian to Fortenan	3	10.7
Maji ya Jumvi to Miritini	3	10.7
Mau Sammit to Kericho	3	10.7
Nyamasaria to Kericho	3	10.7
Total	28	100.0

An inquiry was made into the designation of the respondents' in the respective projects and the results are shown in Table 4.2 below.

Table 4.2 Designation of Respondents

	Designation	Frequency	Percent
Valid	Project engineer	6	21.4
	Resident engineer	8	28.6
	Project manager	4	14.3
	Assistant project manager	3	10.7
	Accountant	1	3.6
	Site agent	2	7.1
	Project director	1	3.6
	Contract manager	1	3.6
	Project manager for the employer	1	3.6
	Others	1	3.6
	Total	28	100.0

The designation of the respondents ranged from project engineers, resident engineers, projects managers, assistant projects engineers to site agents and contract managers amongst others. As depicted in Table 4.2, most of the respondents were resident engineers (28.6 percent) while project engineers constituted 21.4 percent of the respondents. This fair distribution of the respondents implies that the data was collected from well informed participants in the various road construction project under study, hence the reliability.

The study sought to investigate the academic and professional qualifications of the respondents and the results are presented in Table 4.3. According to the results in Table 4.3, 78.6 percent of the respondents had at least a bachelor's degree in the relevant engineering field with both Bachelor of Science in civil engineering and Master of Science in civil or technology at 39.3

percent while 3.6 percent had a master of science in transportation. This implied that most respondents were knowledgeable in road construction technicalities and associated issues. However, the fact that only 14.3 percent of the respondents had managerial and project management qualifications in addition to the engineering qualifications need to be addressed. This implies that the road projects were largely managed by managers with limited project management skills.

Table 4.3 Academic and Professional Qualification of the Respondents

	Qualification	Frequency	Percent
Valid	BSC - Civil Engineering	11	39.3
	MSC - Civil and Technology	11	39.3
	Project or Business Management	4	14.3
	MSC Transport and Road Engineering	1	3.6
	Others	1	3.6
	Total	28	100.0

In the same context, the study sought to investigate the working experience of the respondents in road construction project and the findings are indicated in Table 4.4.

Table 4.4 Working Experience

	Working Experience (Years)	Frequency	Percent
Valid	1 to 5	13	46.4
	6 to 10	7	25.0
	11 to 15	2	7.1
	Over 20	6	21.4
	Total	28	100.0

From Table 4.4, 46.4 percent of the respondents had between 1 and 5 years' experience while 25 percent of them had between 6 and 10 years of working experience. The same findings indicate that 7.1 percent had between 11 and 15 years' experience. According to the findings, 21.4 percent of the respondents had over 20 years' experience. This implies that the data was collected from individuals with substantial experience in road construction, further affirming the confidence in the data collected.

#### 4.3 Extent of Contribution to Cost and Time Overruns

The calculated mean and standard deviations of the respondents to the extent of contribution of the causes of delay and cost are shown in Table 4.5 below. The questionnaires sent to the respondents had listed 57 causes of time and cost overruns in road construction projects. From 4.5, poor or inadequate specifications in the contract had the highest mean of 3.68 implying that

Table 4.5 Descriptive Statistics – Variables Extent of Contribution

Statistic   Stat	Table 4.5 Descriptive Statistics – Variables Exte	N	Std. Deviation

	Valid N (listwise)	28	1./143	.13307	.00777

it affects the time and cost overrun to a large extent based on the Likert scale. The same findings indicate that poor organizational communication systems had the lowest mean of 1.71 and standard deviation of 0.15 indicating that it affects time and cost overruns to a small extent. Since the response to each statement varied from 1 to 4, a mean score of 2.4 (60 percent) was considered to affect cost and time. Based on this criteria, poor or inadequate specifications in the contract; delayed payments to contractors; employer cash flow problems; increase in scope of work; inaccuracy of bill of quantities; inadequate planning by the client; relocation of services; underestimation of project durations; unforeseen ground conditions; unpredictable weather; fluctuations in material, labour and plant costs; foreign exchange rate fluctuations; delay of access to site; poor resource planning by contractor; increase in scope of work; and poor cost control mechanisms were causes of delay in cost and time.

Other variables included planning capabilities and effective resource coordination, planning capabilities and effective resource coordination, contractor cash flow problems, contractor's lack of professional project management skills, environmental challenges, poor site management, inappropriate organizational structure, government bureaucracy, lack of adequate scope and works specification, delays in approvals by engineer, dispute between key stakeholders, ambiguous client budgets, inadequate supervision of road projects, political interference, poor construction methods/approaches, low labour productivity, slow speed of decision-making, ability of the organization to manage risk, risk allocation, lack of sufficient contractor experience, poor contract management, cost increase due to environmental restrictions, poor sub-contracting, shortage of materials, finance and payment of completed works, procurement obstacles, delays in release of drawings, complex interfaces of various, work packages, lack of top management support, labour disputes, poor relationship between the lead engineers/managers and the contractor, inappropriate client organizational structure, poor safety measures, corruption, lack of adequate quality management systems, poor quality control, length of the project, poor infrastructure, for example telecommunications, access roads, Llack of motivation among the project team managers, client relations with financier, poor interpretation of requirements, engineer's lack of adequate professional project management skills and poor organizational communication systems.

The standard deviation, varied between 0.79 and 1.21, for response scale of 1 to 4 a standard deviation of more than 1 was considered high. Twenty-eight variables (49.12 percent) had standard deviations of more than 1. This variability can be attributed to the degree of variation of the occurrences of the causes of time and cost overruns in the projects, technical and managerial capacity of the project's team.

#### 4.4 Relative Importance to Cost and Time Overruns

This approach was applied to analyse part B of the questionnaire where respondents were required to rate the chances of occurrence for each variable. The relative importance index was computed as  $RII = \frac{\sum w}{A*N}$ 

where:

W = weighting as assigned by each of the respondent in a range of 1 to 3, where 1 implied "low", 2 implied "medium" and 3 implied "high";

A = highest weight (3);

N = total number in the sample

The RII indicator is a measure of the likelihood or recurrence of the variable from the respondent's point of view. The indices can, therefore be used to determine the rank of each variable and the results are shown in Table 4.6 below.

By applying a criterion of over 60 percent or RII mean score of 1.8 to identify variable that had higher rating for occurrence, in appropriate organizational structure, unforeseen ground conditions, employer cash flow problems, poor sub-contracting, increase in scope of work, inadequate planning by the client, poor cost control mechanisms, lack of sufficient contractor experience, increase in scope of work, contractor cash flow problems, length of the project, unpredictable weather, underestimation of project durations, delayed payments to contractors, inaccuracy of bill of quantities, poor resource planning by contractor, relocation of services, shortage of materials, finance and payment of completed works, fluctuations in material, labour and plant costs, poor relationship between the lead engineers/managers and the contractor, corruption, political interference, poor contract management, dispute between key stakeholders, cost increase due to environmental restrictions, environmental challenges, government bureaucracy, Poor infrastructure e.g. telecommunications, access roads, poor safety measures, poor or inadequate specifications in the contract, low labour productivity, lack of top

Table 4.6 Relative Importance Indices for the Variables

Relative Importance	N	Sum	Mean	RIIs
In appropriate organizational structure	28	76.00	2.7143	0.762
Unforeseen ground conditions	28	75.00	2.6786	0.702
Employer cash flow problems	28	71.00	2.5357	0.810
Poor sub-contracting	28	68.00	2.4286	0.714
Increase in scope of work	28	66.00	2.3571	0.619
Inadequate planning by the client	28	65.00	2.3214	0.571
Poor cost control mechanisms	28	64.00	2.2857	0.655
Lack of sufficient contractor experience	28	63.00	2.2500	0.583
Increase in scope of work	28	62.00	2.2143	0.679
Contractor cash flow problems	28	61.00	2.1786	0.690
Length of the project	28	61.00	2.1786	0.583
Unpredictable weather	28	60.00	2.1429	0.667
Underestimation of project durations	28	59.00	2.1071	0.714
Delayed payments to contractors	28	58.00	2.0714	0.667
Inaccuracy of bill of quantities	28	58.00	2.0714	0.643
Poor resource planning by contractor	28	57.00	2.0357	0.619
Relocation of services	28	57.00	2.0357	0.929
Shortage of materials, finance and payment of completed works	28	56.00	2.0000	0.643
Fluctuations in material, labour and plant costs	28	56.00	2.0000	0.548
Poor relationship between the lead engineers/managers and the contractor	28	55.00	1.9643	0.619
Corruption	28	55.00	1.9643	0.940
Political interference	28	54.00	1.9286	0.560
Poor contract management	28	54.00	1.9286	0.560
Dispute between key stakeholders  Cost increase due to environmental restrictions		53.00	1.8929	0.595
Environmental challenges	28 28	53.00 53.00	1.8929	0.464 0.714
Government bureaucracy	28	52.00	1.8929 1.8571	0.714
Poor infrastructure e.g. telecommunications, access roads	28	52.00	1.8571	0.043
Poor safety measures	28	52.00	1.8571	0.780
Poor or inadequate specifications in the contract	28	52.00	1.8571	0.607
Low labour productivity	28	52.00	1.8571	0.571
Lack of top management support	28	52.00	1.8571	0.667
Foreign exchange rate fluctuations	28	52.00	1.8571	0.881
Poor site management	28	51.00	1.8214	0.690
The ability of the organization to manage risk	28	51.00	1.8214	0.667
Engineer's lack of adequate professional project management skills	28	50.00	1.7857	0.821
Lack of adequate scope and works specification	28	50.00	1.7857	0.690
Lack of motivation among the project team managers	28	49.00	1.7500	0.655
Contractor's Lack of professional project management skills	28	49.00	1.7500	0.643
Planning capabilities and effective resource coordination	28	49.00	1.7500	0.738
Poor quality control	28	48.00	1.7143	0.643
Labour disputes	28	48.00	1.7143	0.595
Risk allocation	28	48.00	1.7143	0.762
Poor organizational communication systems	28	47.00	1.6786	0.655
Ambiguous client budgets	28	47.00	1.6786	0.774
Complex interfaces of various work packages	28	47.00	1.6786	0.643
Delays in release of drawings	28	47.00	1.6786	0.583
Clint relations with financier	28	47.00	1.6786	0.536
Procurement obstacles	28	47.00	1.6786	0.738
Inappropriate client organizational structure	28	46.00	1.6429	0.845
Delays in approvals by engineer	28	46.00	1.6429	0.595
Poor construction methods/approaches	28	45.00	1.6071	0.643
Delay of access to site	28	45.00	1.6071	0.786
Poor Interpretation of requirements	28	43.00	1.5357	0.595
Lack of adequate quality management systems	28	43.00	1.5357	0.595
Slow speed of decision-making	28	43.00	1.5357	0.595

management support, foreign exchange rate fluctuations, poor site management and ability of the organization to manage risk were seen as the most frequent variables to occur during implementation of similar road projects in Kenya.

## 4.5 Comparison Between Extent of Contribution and Relative Importance Index

In order to relate the respondents' rating of the extent of contribution to rating on each occurrence of each variable, a comparison using the mean score of rating on the extent of contribution and relative importance was examined as depicted in Table 4.7 below. A scatter plot of contribution index versus RII was done as shown in Figure 4.1 below to examine the bivariate relationship between the two rankings.

Figure 4.1 Contribution Index Against Relative Importance Index

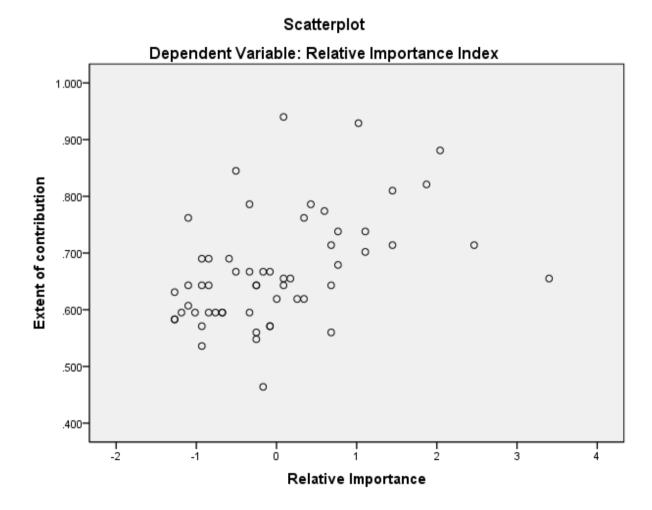

Table 4.7 Comparison of Extent of Contribution to Frequency of Occurrence of Variables

Poor or inadequate specifications in the contract	Extent of Contribution	Extent Index	Rank	RII	Rank
Employer cash flow problems	Poor or inadequate specifications in the contract	3.6786	1	0.655	28
Increase in scope of work   3,0357   4   0,821   5   0,714   15   Inaccuracy of bill of quantities   2,2871   5   0,714   15   Inaccuracy of bill of quantities   2,2871   6   0,810   6   Relocation of services   2,7143   7   0,702   17   17   Underestimation of project durations   2,27143   7   0,702   17   Underestimation of project durations   2,27143   7   0,702   17   Underestimation of project durations   2,27144   8   0,738   12   Unfrowesen ground conditions   2,2714   10   0,738   13   13   Fluctuations in material, labour and plant costs   2,2714   11   0,679   21   0,643   31   18   19   19   19   19   19   19   1	Delayed payments to contractors	3.2857	2	0.714	16

The Pearson moment coefficient of correlation, which is a measure of the strength of the linear relationship between the two variables, was 0.6133 and the correlation was significant at 0.01 level (1-tailed). This observation can be attributed to the fact that in the respondents' opinion, factors considered significant in contributing to time and cost overruns were also perceived as having a high frequency of occurrence in future road projects.

#### 4.6 Variables Influencing Time and Cost Overruns

To establish the multivariate interrelationships among the variables identified as significant contributors to time and cost overruns, and to further explore the structure of the data, the Principal Component Analysis (PCA) technique was applied. According to Kleinbaum, Kupper and Muller (1988), PCA enables a researcher explain relationships among several difficult-to-interpret, correlated variables in terms of a few conceptually meaningful, relatively independent factors. The technique's appropriateness for factor extraction was examined through the Keiser-Meyer-Olkin (KMO) static.

Sixteen highly ranked variables based on their extent of contribution indices (mean scores) were selected for factor analysis since their extent of contribution were perceived above "moderate extent" to "very large extent". Their mean scores approximated to or more than 2.4 (60 percent) on scale of 1 to 4. Before factor extraction, there were 16 eigenvectors, which corresponded to the highly ranked factors causing time and cost overruns. Six principal components were extracted for time and cost overruns causes. Observation indicated that the six decision factors accounted for 75.031 percent of the total variation in time and cost overruns as shown in Table 4.8.

To achieve factor loadings that were easier to interpret, varimax rotation was done. Table 4.8 shows extracted factors and their respective variables that have loadings greater than 0.5. As indicated in Table 4.9, the variables were then clustered into six most influential factors causing time and cost overruns; increase in scope of work; delayed payments to the contractor; poor cost control; foreign exchange rate fluctuations; poor or inadequate specifications in the contract; and unpredicted weather. Increase in scope of work had the greatest influence on time and cost overruns since it accounted for up to 24.2 percent of the total variation followed by delayed payments to the contractor (15.6 percent). Poor cost control was next accounting for 10.7 percent

and foreign exchange rate fluctuations at 10 percent. The fifth most influential factor was poor or inadequate specifications in the contract, which account for 8.1 percent of the variation. Unpredicted weather was the least influential of the six variable variables accounting for 6.5 percent of the total variation in time and cost overruns.

#### 4.7 Relationship Between Variables and Time and Cost Overruns

A multiple linear regression model was used to establish the relationship between the various time and cost overruns factors in the selected road projects. Time overruns constituted the project time extension in months while cost overrun was measured by the total cost deviations from the initial project cost estimates as indicated in Table 4.10.

Table 4.10 Time and Cost Overruns

Project Name	Cost Deviation (Million KShs)	Time Deviation (Months)
Eldoret to Webuye	2,005.55	36
Sotik to Ndanai	225.73	11
Marsabit to Turbi	320.12	25
Londian to Fortenan	871.88	29
Maji Ya Chumvi to Miritini	291.92	2
Homabay to Mbita	499.81	27
Timboroa to Eldoret	2,100.05	10
Kendu Bay to Homa Bay	0	9
Mau Summit to Kericho	320.12	25
Nyamasaria to Kericho	2,320.97	20

Time overruns (dependent variable) was measured by the deviation in months from the planned project completion time and the results are shown in Table 4.11.

		oredicta other	able	1.593	1.959	•	163	.8	13	.002	-2.480	5.666

From Table 4.11 the coefficient of determination ( $R^2$  Square) was 0.897 indicating that 89.7 percent of the variation in time overruns can be attributed to the factors that cause time and cost overruns in road construction projects in Kenya. As shown in Table 4.11 the F static was 1.018 with a significant p – value of 0.001. This implies that the impact of the various factors causing time overruns was significant at 5 percent confidence level. In addition, Table 4.11 shows which factors were significant. All the factors were significant (p – value less than 0.05) and apart from foreign exchange rate fluctuations, all the factors had a positive impact on time overruns in road construction projects in Kenya. From Table 4.11, the predictive equation was TOR = 3.499ISW + 1.453DPC + 3.044PCM - 1.757FEL + 0.648ISC + 1.593UPW where;

TOR = Time Overruns (in months)

ISW = Increase in scope of work

DPC = Delayed payments to contractors

PCM = Poor cost control mechanisms

FEL = Foreign exchange rate fluctuations

ISC = Poor or inadequate specifications in the contract

UPW = Unpredictable weather

The predictive equation indicates that, a unit increase in the increase in scope of work, delayed payments to contractors, poor cost control mechanisms, poor or inadequate specifications in the contract, and unpredictable weather will lead to 3.5, 1.5, 3, 0.6 and 1.6 months increase, respectively in time overruns in road construction projects and an increase by one unit in foreign exchange fluctuation rates will read to a decrease in time overruns in road construction projects by 1.8 months.

The six most significant factors causing cost overruns were regressed against the total project cost deviations to establish the relationship between the factors and cost overruns. Cost overruns (dependent variable) was measured by the deviations in total project cost in Kenya Shillings and the results are presented in Table 4.12 below. From Table 4.12 the coefficient of determination ( $R^2$  Square) is 0.794 indicating that 79.4 percent of the variation in cost overruns was by the factors that cause time and cost overruns in road construction projects in Kenya. In addition, the overall model was significant since p - value was less than the level of confidence (0.001 <  $\infty$  = 0.05.

Table 4.12 also shows which factors were significant and all the factors were significant (p – value less than 0.05) and had a positive impact on cost overruns in road construction projects in Kenya. From Table 4.12, the predictive equation was COR = 9.6728 + 3.4718SW + 2.7138DPC + 0.6419PCM + 0.9545FEL + 1.2439ISC + 0.8810UPW

where; COR = Cost Overruns (in million Kenya shillings)

The predictive equation indicates that, a unit increase in the increase in scope of work, delayed payments to contractors, poor cost control mechanisms, foreign exchange fluctuation rates, poor or inadequate specifications in the contract, and unpredictable weather will lead to 3.5, 2.7, 0.6, 1, 1.2 and 0.9 increase, respectively in cost overruns in road construction projects.

# CHAPTER FIVE: SUMMARY, CONCLUSION AND RECOMMENDATIONS

#### 5.1 Introduction

This study sought to investigate the factors that cause time and cost overruns in road construction projects in Kenya. A descriptive survey of project personnel drawn from contractors, consultant and KeNHA staff involved in 10 recently completed road projects was conducted to establish the factors that had significantly contributed to time and cost overruns during the implementation of the respective road projects. This chapter presents summary of the findings, conclusion and recommendations of the study.

#### 5.2 Summary

The study was guided by three objectives; the first objective of the study was to identify variables influencing road construction time and cost overruns in Kenya. The study focused on 57 variables that were deemed to have had significant contribution to time and cost overruns. The analysis of the variables' extent of contribution to overruns gave 16 highly ranked variables based on their extent of contribution indices (mean scores) since their extent of contribution were perceived above "moderate extent" to "very large extent". Their mean scores were approximated to or more than 2.4 (60 percent) on a scale of 1 to 4. According to the findings, poor or inadequate specifications in the contract had the most influence on time and cost overruns. Others were delayed payments to contractors, employer cash flow problems, increase in scope of work, inaccuracy of bill of quantities, inadequate planning by the client, relocation of services, underestimation of project durations, unforeseen ground conditions, unpredictable weather, fluctuations in material, labour and plant costs, foreign exchange rate fluctuations, delay of access to site, poor resource planning by contractor, increase in scope of work, and poor cost control mechanisms.

The PCA was applied to categorize the various variables for easy analyzability and identify any multivariate inter-relationships among the 16 variables identified as contributors to time and cost overruns. Six factors causing time and cost overruns were extracted; increase in scope of work, delayed payments to the contractor, poor cost control, foreign exchange rate fluctuations, poor or inadequate specifications in the contract, and unpredicted weather. Among these factors, increase

in scope of work had the most influence on the time and cost overruns followed by delayed payments to the contractor while unpredicted weather had the least influential of the six factors accounting for the total variation in time and cost overruns in the road projects.

The second objective of the study was to determine the relative importance of the variables causing time and cost overruns in road construction projects. The study sought to elicit those factors that were considered to have high frequency of occurrence in future on similar project environment. The relative importance of these factors in contributing to time and cost overruns on future projects was achieved through ranking using the extent of contribution index and in particular RII and 35 factors were identified as having a high chance of occurrence

In order to examine the bivariate relationship between the two rankings, a scatter plot of correlation coefficients was done and the plot indicated a high positive correlation between the two rankings. This observation can be attributed to the fact that in the respondents' opinion, factors considered significant in contributing to time and cost overruns were also perceived as having a high frequency of occurrence in future road projects.

The third objective of the study was to determine the quantitative impact of time and cost overruns in road construction projects in Kenya. The quantitative assessment of the impact of the variables involved a multiple linear regression analysis of the six most significant factors contributing to time and cost overruns and two regression models were established for both time and cost overruns. The regression analysis indicated that most (89.7 percent) of the variations in time overruns were attributed to unpredictable weather, foreign exchange rate fluctuations, poor cost control mechanisms, increase in scope of work, delayed payments to contractors and poor or inadequate specifications in the contract with increased scope of work having the biggest impact on time overruns in road construction projects. Apart from foreign exchange rate fluctuations, which had a negative coefficient, all the other factors had positive coefficients. On the relationship between the factors and cost overruns, the study established that the six factors had a significant impact on cost overruns over the period under study accounting for 79.4 percent of the total variation in cost overruns and they all had positive coefficients.

#### 5.3 Conclusion

The findings of this study corroborate past empirical literature on challenges associated with successful implementation of construction projects as outlined in the literature review. Although several factors have contributed to time and cost overruns in road construction projects in Kenya, the most significant of them include unpredictable weather, foreign exchange rate fluctuations, poor cost control mechanisms, increase in scope of work, delayed payments to contractors and poor or inadequate specifications in the contract with increased scope of work having the biggest impact on time and cost overruns in road construction projects.

From this study, the above variables have a high chance of occurrence, hence the need for respective agencies to devise ways of mitigating their impact on future road projects. Increase in scope of work can be considered to have been the lead factor in contributing to time and cost overruns on the road projects. The other factors in order of significant were delayed payments to contractors, poor or inadequate specifications in the contract, foreign exchange rate fluctuations, unpredictable weather and poor cost control mechanisms. Based on this study, it can be inferred that the variation in time and cost overruns can be attributed to the six factors above and that there exists a positive relationship between these factors and time and cost overruns. From the findings of this study, it can also be concluded that the occurrence of these factors is contextual, hence will largely depend on the project environment.

#### 5.4 Recommendations

The findings of this study portray challenges facing the implementation of infrastructural projects in Kenya and their economic impact; consequently, the study makes the following recommendations. At macro-level, policy makers both at county and national levels formulate strategies towards mitigating the impact of these factors given the fact that most of them have a high chance of recurring in future road projects. There is need for the line ministries and other agencies allied to infrastructural development in Kenya to establish enabling factors for successful implementation of road and other infrastructural projects in Kenya.

At micro-level, contractors, consultancies, and other stakeholders need to do proper definition of project scope and apply modern project management tools given the fact that increase in scope of work was lead factor in contributing to time and cost overruns on road projects. At the

preliminary stages, enough material and time resources should be committed to ensure that adequate feasibility studies are conducted to avoid duality. This will go a long way in ensuring that specifications are well prepared, scope is well defined, proper material and time estimates are done. In addition, geographical and socio-economic risk determinant like weather, inflation and exchange rates should be factored in the initial planning stages.

#### 5.5 Limitations of the Study

The study sought to investigate the factors that cause time and cost overruns in road construction projects in Kenya. It is clear that a study of this magnitude should include a survey of sizeable number of road projects over a wider time span of say, 10 years. However, time and material resources did not make this feasible and for this reason, the study concentrated on 10 major roads completed in the recent past under KeNHA.

In addition, the study period for this study was short for a study of this nature. The researcher had to juggle between work and the field, particularly during data collection. This was a major hindrance particularly in ensuring that the research work did not hamper the performance and productivity of the researcher at the work place. At the same time, some of the respondents were non-committal posing major challenge in the field during the data collection.

#### **5.6** Suggestions for Further Research

Studies involving confirmatory factor analysis will need to be carried out to further test the model so established and to confirm the findings of the study. Further studies can be conducted to test and confirm factor loadings in different infrastructural projects so as to establish the validity and strength of the model. Having identified the factors causing time and cost overruns in road projects in Kenya, there is need for further research to focus on the critical success factors in the implementation of road construction projects in Kenya.

The fact that the degree to which various factors affects time and cost overruns varies from one road project to the other, calls for further research efforts to identify optimal project management practices and on the possibility of setting benchmarks in Kenya's construction industry. The need for further research into this aspect of project management is further compounded by the fact that operations management practice is a relatively new phenomenon particularly in the building

sector in Kenya	where m	ost project	managers	are	oriented	towards	engineering	professional	and
academic qualifi	cations.

OFFICE OF THE CHAIRMAN, DEPARTMENT OF BUSINESS ADMINISTRATION

**To:** Whom it may concern

From: Chairman, Business Administration Department

**Date:** August, 15<sup>th</sup>, 2015

SUBJECT: ASSISTANCE IN DATA COLLECTION

This is to certify that Stanley W. Mwawasi of Registration No. D61/70872/2014 is registered in

the Masters of Business Administration Programme at the School of Business, University of

Nairobi. In partial fulfilment of the requirements for the award of the degree, the candidate is

required to undertake an empirical study to enable him write a thesis. To this end, Stanley W.

Mwawasi is carrying out a study "TIME AND COST OVERRUNS IN ROAD

CONSTRUCTION PROJECTS IN KENYA UNDER KENYA NATIONAL HIGHWAYS

**AUTHORITY**"

This is to request you to offer him the necessary support to enable him collect primary data,

which will be used for academic purposes only.

Thank you.

Chairperson

**SCHOOL OF BUSINESS - UNIVERSITY OF NAIROBI**

### UNIVERSITY OF NAIROBI

SCHOOL OF BUSINESS MBA PROGRAMME

Telephone: 020-2059162 Telegrams: "Varsity", Nairobi Telex: 22095 Varsity

P.O. Box 30197 Nairobi, Kenya

DATE 21/10/2015

#### TO WHOM IT MAY CONCERN

The bearer of this letter STANLEY W. MWAWAS I.

Registration No. D 61 / 70872 / 2014

is a bona fide continuing student in the Master of Business Administration (MBA) degree program in this University.

He/she is required to submit as part of his/her coursework assessment a research project report on a management problem. We would like the students to do their projects on real problems affecting firms in Kenya. We would, therefore, appreciate your assistance to enable him/her collect data in your organization.

The results of the report will be used solely for academic purposes and a copy of the same will be availed to the interviewed organizations on request.

Thank you.

PATRICK NYABUTO

SCHOOL OF BUSINESS

MBA ADMINISTRATOR
