Radiation protection and the unborn child

Abstract:

A prospective study was carried out at Kenyatta National Hospital (KNH) between June 1987 and September 1988 to look at some aspects of obstructive jaundice in patients above 12 years of age. Screening for cases was done by use of abdominal ultrasonography. A total of 20 cases (11 females, 9 males) were diagnosed. Carcinoma of the head of pancreas accounted for 55% of cases of the obstruction, followed by gallstones (10%), hepatocellular carcinoma (10%) and gall bladder tumour (10%).
